ABSTRACT. Nanolaminates are new class of promising nanomaterials with outstanding properties. Here we explored on the tuning of structural properties and the enhancement of electronic and optical properties of 1D PAN ZnO/Al₂O₃ nanolaminates designed by Atomic Layer Deposition (ALD) and electrospinning. The influence of ZnO/Al₂O₃ bilayer thicknesses on the fundamental properties of 1D PAN ZnO/Al₂O₃ nanolaminates has been investigated. Due to the quantum confinement effect, the shift of XPS peaks to higher energies has been observed. Work function of Al₂O₃ was mostly independent of the bilayers number whereas the ZnO work

function decreased with an increase of the bilayer number. Photoluminescence of the 1D PAN ZnO/Al₂O₃ nanolaminates corresponded to emission bands in ZnO nanolayers. Due to quantum confinement and surface band bending, no excitonic peaks were observed. The defect emission band was affected by the band bending and defect concentration. The enhanced photoluminescence of the 1D PAN ZnO/Al₂O₃ nanolaminates allows applications in optical (bio)sensing field.

KEYWORDS. Nanolaminates, atomic layer deposition, electrospinning, Work function, photoluminescence

INTRODUCTION

Nanolaminates are new class of promising nanomaterials with well-tailored properties. These materials are obtained by alternating layers with an individual thickness on the nanometer scale of different materials.¹ They manifest outstanding advanced mechanical,² electrical and optical properties¹ which depend from the constituent materials forming these nanolaminates. Zinc Oxide (ZnO) which can be incorporated in the nanolaminate material is a n-type semiconductor with wide band gap value (3.3 eV) and high exciton binding energy (0.06 eV). It also exhibited room temperature photoluminescence in UV-Vis region.^{1, 3} Among the different techniques to elaborate oxides based nanolaminates, Atomic Layer Deposition (ALD) is a powerful tool to fabricate different oxide materials.⁴⁻⁵ It is based on two self-limiting surface reactions which allow growing continuous, smooth, and conformal ultrathin film on high aspect ratio and complex substrates such as the 1D nanostructures with a precise dimensional control. This paper deals with the investigation of electronic and optical Properties of ZnO/Al₂O₃ Nanolaminate Coated Electrospun Nanofibers.

The design of Al₂O₃/ZnO nanolaminates as well as ZnO thin film doped with Al was widely investigated by ALD.^{2, 6-9} The ZnO deposited on Al₂O₃ thin films in the Al₂O₃/ZnO

nanolaminates demonstrated a different growth direction in comparison to single ZnO thin film.¹⁰ ZnO demonstrates as well a change from amorphous to nanocrystalline with the increase of the bilayers thickness where Al₂O₃ layer remains amorphous.² The change of the growth direction, the crystallinity and the Al doping influence the optical,^{1, 11} electrical¹² and mechanical properties² of the deposited thin films. Recently we investigated the optical and the structure properties of ZnO/Al₂O₃ nanolaminates deposited on Si substrates by Atomic Layer Deposition (ALD).¹ We demonstrated the amorphous-to-crystalline phase transitions of ZnO in ZnO/Al₂O₃ nanolaminates as well as the quantum confinement and size dependent room temperature photoluminescence.¹ It was shown a correlation between structure (grain size and layer thickness) and optical (extinction coefficient and refractive index), pointing to the influence of growth conditions on the fundamental properties of the nanolaminates.¹

Different 1D nanostructures such as Carbon Nanotubes (CNTs) and polymer fibers have been investigated in order to design core/shell nanostructures using ALD of metal oxides.¹³⁻¹⁷ Different studies were performed for the growth of oxides of Carbon nanotubes. Stafona *et al.* reported the influence of CNTs type and the defect concentration on the ALD coating.¹⁷ For low defect concentration, ALD coating cannot be realized. The functionalization of CNTs surface is needed to promote the nucleation of the oxide film. Carboxyl and hydroxyl groups are formed on the CNTs surface to initiate the ALD growth. Kemnade *et al.* showed that conformal growth of ALD ZnO layer on CNTs requested the modification of the CNTs with aromatic linking agents.¹⁴ Lin *et al.* reported on the importance of CNT functionalization before deposition of ZnO nanolayers by ALD.¹⁵ Kayaci *et al.* reported that ALD ZnO layers provided a conformal coating of nylon fibers.¹³ However, Oldham *et al.* demonstrated that TMA and DEZ precursors could chemically react with polyamide-6 (PA-6) nylon nanofibers destroying their physical properties.¹⁶ Therefore, the conformal and uniform ALD coating on 1D nanostructures could be achieved by the right choice of the core chemical composition and surface state of the 1D nanostructures. PAN nanofibers are good chemically stable material for 1D core/shell

nanostructure design.¹⁸ PAN nanofibers have been successfully used for chemical deposition of different metal nanoparticles on their surface. It was shown that PAN nanofibers have good mechanical and thermal stability. The adsorption sites present on the surface of the PAN fibers would facilitate the nucleation of the metal oxide layers by ALD. Thus, integration of metal oxide ALD technique and PAN nanofibers has a good perspective.

Previously, we have reported on the fabrication of three-dimensional polyacrylonitrile /ZnO material prepared by the combination of electrospinning and atomic layer deposition (ALD) as new material with large surface area to enhance the optical properties.¹⁹⁻²⁰ The study of room temperature photoluminescence (PL) spectrum exhibits peak intensity which enhance by a factor of 2000 compared to a flat Si substrate.²⁰ In the present work, we report on the enhancement of electronic and optical properties of 1D organic core with ZnO/Al₂O₃ nanolaminates shell nanostructures. The influence of structure parameters of ZnO/Al₂O₃ nanolaminates (thickness, grain size, number of bilayers, defect concentration) on the main electronic (Work Function) and optical (photoluminescence and band gap) properties will be discussed. The enhancement of electronic and optical properties will allow application in different fields such sensors and biosensors.

MATERIALS AND METHODS

Polyacrylonitrile (PAN) nanofibers have been elaborated by electrospinning technique to be a template for the nanolaminates design by Atomic Layer Deposition (ALD).

1. Electrospinning of PAN nanofibers

Polyacrylonitrile PAN ($M_w = 150000$) and Dimethylformamide (ACS reagent, $\geq 99.8\%$) were purchased from Sigma Aldrich. Polyacrylonitrile (10 wt% PAN) was dissolved in dimethylformamide (DMF). The electrospinning solution was maintained under agitation for 1 hour and then heated in an oil bath at 80°C for 10 min. The used electrospinning machine was a

home-made device using an HPx 600 605 generator (physical instruments) and a KDS 100 syringe pump. The polymer solution was electrospun in ambient air atmosphere under an applied voltage of 25 kV with a flow rate of 3 mL h⁻¹ using a 0.7 mm diameter syringe connected to the positive output of the generator. A fix collector was placed 25 cm from the tip of the syringe and was related to the negative output of the generator. The droplet was transformed to a Taylor cone due to the electrostatic field applied between the syringe and the collector. The evaporation of the solvent during the process induces the formation of a net of submicron fiber.

2. ALD deposition of nanolaminates

Diethyl Zinc (DEZ) ($\text{Zn}(\text{CH}_2\text{CH}_3)_2$, 95% purity, CAS: 557-20-0) and Trimethylaluminum (TMA) ($(\text{CH}_3)_3\text{Al}$) 98% purity, CAS: 75-24-1) were purchased from Sigma Aldrich. A custom made ALD reactor was used for the synthesis of ultrathin $\text{Al}_2\text{O}_3/\text{ZnO}$ nanolaminates. ALD was performed using sequential exposures of TMA (DEZ) and H_2O separated by a purge of Argon with a flow rate of 100 sccm. The deposition regime for ZnO and Al_2O_3 consisted of 0.2 s pulse of TMA (DEZ), 30 s of exposure to TMA (DEZ), 30 s of purge with Argon followed by 2 s pulse of H_2O , 30 s of exposure to H_2O and finally 40 s purge with Argon. $\text{Al}_2\text{O}_3/\text{ZnO}$ ultrathin nanolaminates with different numbers of cycles were deposited on electrospun PAN nanofibers (Table 1). The deposition temperature was fixed to 100 °C. We note here that in contrast to the deposition of thin films on flat surfaces, the reactants had to diffuse into the high-aspect-ratio structures. Therefore an exposure time should be added and adapted in order to assure the conformal coating of the PAN nanofibers. GPC of ~0.2 nm/cycle has been observed for Al_2O_3 and ZnO. These values are consistent with what has been reported elsewhere by Karvonen *et al.*⁹ on ZnO/ Al_2O_3 nanolaminates. The difference between the GPC of Al_2O_3 reported on single Al_2O_3 layers and the ZnO/ Al_2O_3 nanolaminates has been attributed to the higher surface area of the rough crystalline ZnO interfaces.⁹

3. Structural, chemical and Optical characterizations

Structural and chemical compositions of all PAN-nanolaminates were analyzed by transmission electron microscopy (TEM). Images were obtained with a JEOL ARM 200F high-resolution transmission electron microscope (200 kV) with an EDX analyzer (JED2300, at least 30 accumulations, matrix 512x512 points in STEM mode). Dark and bright field detectors were used.

FTIR spectra were obtained with the Bruker VERTEX 70v vacuum spectrometer using the RT-DLaTGS detector (spectral resolution of 4 cm^{-1}). X-Ray diffraction measurements were performed with PANalytical Xpert-PRO diffractometer equipped with a X'celerator detector using Ni-filtered Cu-radiation. Surface structural and chemical properties of PAN-nanolaminates were analyzed by means of the XPS/UPS technique mounted within the Omicron Nanotechnology multiprobe UHV system, using a monochromatized Al-K α X-ray as the excitation source ($h\nu = 1486.6$ eV) and choosing C 1s (284.6 eV) as the reference line. XPS was conducted under ultrahigh vacuum (10^{-7} Pa). CasaXPS software was used to analyze the XPS data. Optical properties of ultrathin nanolaminates have been studied by photoluminescence spectroscopy (in the spectral range of 370-800 nm). The excitation of luminescence was performed by a solid state laser source (Nd:YAG, 355 nm, 13 mW cm^{-2}). The registration of the emitted spectra was provided by an experimental setup described elsewhere.^{1, 3, 20}

RESULTS AND DISCUSSION

1. Chemical and structural characterizations

TEM images of PAN - Al₂O₃/ZnO nanostructures are presented in Figure 1 (TEM image of the end face of PAN fiber and TEM/EDX mapping in Supporting Information (Figure SI1 and SI2)). The TEM images confirm the conformal coating of the PAN nanofibers by ALD. It is clearly seen the nanolaminates formation (ZnO (dark stripes) and Al₂O₃ (light stripes)). The total thickness of nanolaminates layer is 25 nm (Figure 1d). Lattice fringes seen in high-resolution

TEM images reveal ZnO nanocrystals with (101) and (002) planes (Figure 1a and 1b insets). Using ImageJ software, the grain size and the interplane distances for (101) and (002) lattice planes were calculated (Insets of Figure 1 a, b, c). The grain size was calculated using elliptical shape fitting and the longer axis was used as the grain size. The average grain size for 20 nm, 10 nm and 5.2 nm bilayer thicknesses were 9.8 ± 2.5 nm, 6.5 ± 1.5 nm and 5.3 ± 2.1 nm, respectively. For 2 and 1.2 bilayer thicknesses, the grain size was not determined due to the quality of the image and the resolution of TEM. We suppose that in the case of 20 nm, 10 nm and 5.2 nm bilayer thicknesses, the grains were elongated and limited by the layer thickness. The TEM analysis provided evidence that the Al_2O_3 layers are amorphous for all samples. The ZnO layers are in a polycrystalline phase. The TEM images demonstrate the ability to produce highly uniform layers of nanolaminates covered PAN fibers by the ALD processes.

The Fourier-transform infrared (FTIR) absorbance spectrum is presented in Figure 2a. The FTIR data reveals a presence of the main vibration bands of polyacrylonitrile (PAN) in investigated samples. The bands manifest themselves in the ranges of $2260 - 2240 \text{ cm}^{-1}$ ($\text{C}\equiv\text{N}$ stretch) and $1485 - 1035 \text{ cm}^{-1}$ (C-O and C-C stretch and aliphatic CH-group vibrations of different modes in CH, CH_2 and CH_3). Very sharp and strong peak at 2243 cm^{-1} is assigned to nitrile band. After deposition of $\text{Al}_2\text{O}_3/\text{ZnO}$ nanolaminates, two new bands appear in the $1670 - 1600 \text{ cm}^{-1}$ spectral range which are attributed to carbonyl group vibrations.²¹ In the spectral range $600 - 380 \text{ cm}^{-1}$, the peak at 407 cm^{-1} is visible, which is related to ZnO $\text{E}_{1,\text{TO}}$ phonon mode. With a decrease of the nanolaminate thickness, the ZnO phonon related absorption decreases, and at the 1.2 nm bilayer thickness it is undetectable. This tendency implies the transition from the polycrystalline to amorphous phase of the nanolaminates with low bilayer thicknesses. Similar tendency is shown by XRD spectra recorded from nanolaminates with the same bilayer thicknesses (Figure 2b). The ZnO related XRD peaks essentially decrease with a decrease of bilayer thickness. It is reasonable to assume that amorphous nature of ultrathin nanolaminates required minimum thickness to allow crystallization in a thin film.¹¹ The proposed

crystallization model for ultrathin layers and superlattices is taking into account the interface energies, the thickness of the layers, the melting point of the system, and the bulk amorphous crystallization temperature.²² It was shown that exponential increase of the crystallization temperature leads to the decrease of the minimal thickness at which crystallization occurs. From XRD (Figure 2b), HRTEM and previous studies,^{2, 11} this bilayer thickness value was shown to be 2.5 nm for Al₂O₃/ZnO nanolaminates. So, we assume that close to this value is the point at which the crystallization process starts in Al₂O₃/ZnO nanolaminates. The ZnO grain size decreases with decreasing the bilayer thickness. The amorphous Al₂O₃ layer play the role of stopping layer for ZnO growth. The ZnO layer is forced to renucleate on the underlying amorphous Al₂O₃ layer inducing the decrease of the grain size when the bilayer thickness decreases.

The surface composition and chemical state polymer fiber coated with different bilayers thicknesses of ZnO/Al₂O₃ nanolaminates were studied by XPS (Figure 3). Samples depict zinc (Zn), aluminum (Al), oxygen (O) and carbon (C) components. It is worth to say that no peaks, related to Al were observed for nanolaminates with 10 and 20 nm bilayer thicknesses (Figure 3 d and e). It is related to the limit of the penetration depth of the excitation X-ray photons. As was shown in our previous work, the Auger parameter is a useful tool to determine the stoichiometry and the phase of obtained structures.²³ The main peak of the Zn (LMM) Auger series occurs at kinetic energy of 988±0.5 eV. From this values and Zn 2p_{3/2} binding energy, we calculated the modified Auger parameter α' ($\alpha' = BE(\text{Zn } 2p_{3/2}) + KE(\text{Zn LMM})$, where BE and KE are a binding energy of the core level 2p_{3/2} and a kinetic energy of the Auger transition involving electrons from L3, M45 and M45 core levels) as defined by Wagner. For all samples, our calculations lead to a value of 2009.9±0.5 eV corresponding to ZnO (Wurtzite).²⁴ This indicates the formation of stoichiometric ZnO in all samples.

As the studied samples had a single ZnO layer thickness from 0.6 to 10 nm, their fundamental properties would change from the bulk materials to nanoscale.²⁵ In order to understand the surface role and quantum confinement effects, the energy ranges related to Zn

and O lines were rescaled and analyzed. Figure 4 shows the core level of the Zn 2p spectra. The core level binding energies of Zn 2p_{3/2} and Zn 2p_{1/2} are about 1022.5 ± 0.1 eV and 1045.6 ± 0.1 eV (20 nm bilayer thickness). These peaks indicate the presence of ZnO phase.²⁶⁻²⁹ The binding energy difference (duplet) between these components is about 23.1 ± 0.1 eV which could be attributed to the Zn²⁺ ions in ZnO. From Figure 4 we can see the shift of peak positions to higher energies with the decrease of bilayer thickness. However, the difference of 23.1 eV in all samples indicates the presence of the normal state of Zn²⁺ in the ZnO. The oxygen core level peak behaves similarly (Figure 4 bottom image). The observed phenomenon of XPS size shift can be explained, by growth of surface to volume atoms relation and correspondingly relative increase of dangling bonds on the surface. This leads to change of electronic structure in nanocrystals, resulted in increase of binding energies.^{23, 25, 30}

The XPS peaks were analyzed by de-convolution of peaks using CasaXPS software (**Supporting information; Figure SI3**). It was found, that Zn 2p_{1/2} peak of 1.2 nm bilayer thickness sample was well fitted with one peak, centered at 1045 eV, whereas other samples showed 2 peaks fitting of the corresponding Zn 2p_{1/2} peak. The obtained peaks P1 and P2 were in the range of 1045 ± 0.6 eV and 1044 ± 0.6 eV, respectively. The ratio of Zn 2p_{1/2} (P2)/(P1) increased with a growth of a bilayer thickness, pointing to the decrease of surface-to-volume aspect ratio. The analysis of Zn 2p_{1/2} peaks showed similar results: the main peak was shifted towards lower energies and additional peak at 1022.3 ± 0.6 eV has appeared at the spectra, pointing to the presence of Zn species (interstitials) or Zn-OH in ZnO.³¹

Analysis of O 1S peak has been fitted with 3 peaks, centered at 529.6 ± 0.5 (P1), 531.3 ± 0.2 (P2) and 532.1 ± 0.4 (P3) eV. The present oxygen at XPS spectrum peaks corresponded to chemisorbed surface oxygen and water (P1), surface adsorbed OH and/or oxygen vacancy (P2) and O²⁻ (P3) in ZnO lattice.³² It is worth to say that ratio P2/P3 decreased with the increase of the bilayer thickness, pointing to the improvement of nanolaminates crystallinity and the decrease of the defect concentration.

2. Band gap energy determination

It is well known, that the difference between the onset of inelastic electron losses (E_{loss}) energy and the core level peak (e.g. oxygen peak $-E_O$ 1s) allows one to estimate the energy gap (E_g) of the material.³³ The intersection of the linear-fit line of the measured electron loss spectra near the core level peak and the background “zero” level gives us the onset of inelastic losses occurring in Al_2O_3 .³⁴ Then we can calculate the band gap energy of Al_2O_3 using the formula: $E_g = E_{loss} - E_O$. Applying this theory, we have calculated E_g of Al_2O_3 for PAN-Nanolaminates samples (Figure 5). Following values were obtained: 5.37 ± 0.06 , 5.78 ± 0.09 , 5.88 and 6.01 ± 0.08 eV for PAN-nanolaminates samples with 0.6, 1, 2.6 and 5 nm Al_2O_3 layer thickness, respectively. Unfortunately, it was impossible to calculate the E_g of Al_2O_3 for PAN- Al_2O_3/ZnO (10 nm Al_2O_3 layer thickness) due to the thick top layer of ZnO under the Al_2O_3 layer. Our obtained values of about 6 eV is low compared to the one reported for amorphous Al_2O_3 (8.8 eV).³³ This observation might be explained by the highly defected structure of Al_2O_3 layer in nanolaminates. Upon increasing the Al_2O_3 layer thickness in PAN-nanolaminates, the E_g gradually increases and tends to bulk value.

3. Work function determination

The electronic structure of PAN-ZnO/ Al_2O_3 nanolaminates as a function of the bilayers thicknesses was studied with UV photoelectron spectroscopy (UPS) (He I emission 21.22 eV). The work function (Φ) of the ZnO could be estimated by subtracting the secondary electron cutoff value from the He excitation source of 21.22 eV ($\Phi = 21.22 \text{ eV} - E_{SEC}$). Figure 6 shows the UPS spectra of PAN-ZnO/ Al_2O_3 nanolaminates. The calculated values of Φ are shown in the image. The Φ of ZnO decreases gradually from 5.86 eV (20 nm bilayer thickness) to 5.19 eV (1.2 nm bilayer thickness), which is possibly due to the morphology changes of the top ZnO layers in nanolaminates. The structure of ZnO layer in the 20 nm bilayer thickness sample is

polycrystalline (TEM results; Figure 1), thus, the energy barriers presenting at the border of disorientated ZnO nanocrystallites increases the value of the Φ . The small peak corresponding to Al_2O_3 is also present in the Figure 6. The average value of WF for Al_2O_3 is approximately 4.7 eV and it changes insignificantly.

Work functions of ZnO and Al_2O_3 layers are plotted in Figure 6. The work function of Al_2O_3 was insignificantly changed whereas the ZnO work function significantly decreased with the bilayer thickness.

The change of Φ could be explained by band bending, formed at the upper layer of the nanolaminates (ZnO-air interface) (Figure 7). Electron affinity of ZnO and Al_2O_3 were taken $\chi_{\text{ZnO}}=4.37$ eV and $\chi_{\text{Al}_2\text{O}_3}=1.35$ eV respectively.³⁵⁻³⁶ Fermi level E_F position in each component of the nanolaminates was estimated:

$$E_F = \Phi - \chi \quad (\text{Equation 1})$$

where Φ is a work function.

The conductance band and valence band offsets could be calculated as (Table 2):

$$\Delta E_c = \chi_2 - \chi_1 \quad (\text{Equation 2})$$

$$\Delta E_v = E_{g1} - E_{g2} - \Delta E_c \quad (\text{Equation 3})$$

where $E_{g1,2}$ and $\chi_{1,2}$ are band gap values of Al_2O_3 and ZnO and electron affinity values of ZnO and Al_2O_3 , respectively.

The built in potential V_{bi} between two altering ZnO and Al_2O_3 layers was calculated due to (Table 2):

$$V_{bi} \cdot q = E_{F2} - E_{F1} \quad (\text{Equation 4})$$

where q is an electron charge, E_{F1} and E_{F2} are Fermi level positions in Al_2O_3 and ZnO, correspondently.

To estimate potential drops in ZnO and Al_2O_3 , the Debye lengths in the altering materials were estimated:

$$L_D = \sqrt{\frac{k \cdot T \cdot \epsilon \cdot \epsilon_0}{N_d \cdot q}} \quad (\text{Equation 5})$$

where k , T , ϵ and ϵ_0 are the Boltzmann's constant, absolute temperature, dielectric permittivity of ZnO ($\epsilon=8.5$) and electric constant ($\epsilon_0=8.85 \cdot 10^{-12} \text{ F m}^{-1}$), respectively. The donor concentration in ZnO and Al_2O_3 were taken 10^{23} m^{-3} and 10^{16} m^{-3} , respectively.³⁷⁻³⁸

The estimated Debye lengths were 10^{-8} m and $5 \cdot 10^{-5} \text{ m}$ for ZnO and Al_2O_3 , respectively.

The potential drops in ZnO and Al_2O_3 could be calculated as:

$$\begin{aligned} V_{\text{ZnO}} &= L_{\text{DZnO}} \frac{V_{\text{bi}}}{L_{\text{DAI}_2\text{O}_3} + L_{\text{DZnO}}} \\ V_{\text{Al}_2\text{O}_3} &= V_{\text{bi}} - V_{\text{ZnO}} \end{aligned} \quad (\text{Equation 6})$$

Based on equations (5) and (6) the potential drop in ZnO was 10^{-4} eV . Therefore, the band bending in ZnO at the interface between ZnO and Al_2O_3 is significantly small and the potential drop will be mostly faced in Al_2O_3 layer.

The estimated values of ZnO work function are strongly affected by the surface band bending in the upper ZnO layer. The later could be estimated from equation 7:

$$V_s = \Phi_{1\text{bl}} - \Phi_{20\text{bl}} \quad (\text{Equation 7})$$

Where $\Phi_{1\text{bl}}$ $\Phi_{20\text{bl}}$ are work function of ZnO in 1 bilayer and 20 bilayer samples respectively. The obtained V_s value was 0.64 eV . The depletion width in ZnO could be calculated from the equation 8:³⁹

$$W = \sqrt{\frac{2 \cdot V_s \cdot \epsilon \cdot \epsilon_0}{q \cdot N_d}} \quad (\text{Equation 8})$$

The estimated W value was around 50 nm . Therefore, the upper ZnO layer will be fully depleted and a double barrier structure will be formed on the borders of the ZnO layers, pointing to the confinement of the electrons in ZnO along Z-axis. The observed change of work function in ZnO layers results from the presence of hydroxyl and oxygen groups, adsorbed on ZnO surface. This is corroborated by the band at 3500 cm^{-1} observed in FTIR and XPS analysis. The change of the work function with the increase of the bilayer numbers is affected by 'screening' of the induced

electric field on the surface of the middle Al_2O_3 layers. The part of the depleted ZnO layers will decrease and therefore, the average value of the work function will decrease.

4. Photoluminescence of PAN- Al_2O_3 /ZnO nanolaminates

The photoluminescence of the PAN- Al_2O_3 /ZnO nanolaminates samples showed intense broad visible emission (Figure 8). The deconvolution of the peaks was performed using Gaussian fitting (Supporting Information; Figure SI4). Peaks at 473, 520 and 580 nm have been found. In ZnO, PL appears due to the photogenerated holes and electrons as the equilibrium holes concentration is too low. PL depends on the defects concentration. The visible PL intensity increases with the decrease of the layer thickness due to the growth of defects number. It was shown that PAN, as a template, induces the nucleation of pure ZnO during the growth affecting the optical properties.²⁰ However, in the present work PAN template did not influence the PL of ZnO as since Al_2O_3 layer was the first layer deposited over PAN in all the analyzed samples. It is known that PL of ZnO is sensitive to surface band bending and grain size dimensions.³ Due to the depleted layer, no exciton emission was observed in the samples with 20, 10 and 5.2 nm bilayers thicknesses. Moreover, the strong visible emission has been observed for all samples. The intensity of the measured emission was 1000 folds higher than the PL emission of the nanolaminates, deposited on Si substrates.^{1, 20} The significant increase of the PL was found with the increase of the bilayer numbers. It has been reported that visible PL in ZnO nanostructures is resulted from defects, mostly from Zn and O vacancies and interstitials.^{1, 3, 20} According to that, the observed peaks at 473, 520 and 580 nm could be assigned to neutral, single charged and double charged oxygen vacancies, respectively.^{1, 3, 20} However, the peak at 473 nm could also be related to Zn vacancies.^{1, 3, 20} Measuring only room temperature luminescence, we cannot discriminate the observed peak at 473 nm between two different defect states. However this fact does not change the nature of the emission.

According to XPS data, the number of defects decreased with an increase of the bilayer thickness. Therefore, the 1.2 nm bilayer thickness sample showed the highest photoluminescence. The work function measurements of the samples showed the significant influence of the surface band bending in the upper ZnO layer. The band bending could stimulate the separation of photogenerated electrons and holes, increasing a role of non-irradiative transitions. As shown above, the Al₂O₃ layers ‘screen’ the influence of the surface charge in the upper layer and form heterostructures in which ZnO layers are electron-rich. Besides the decrease of the average value of ZnO work function, the increase of the emission intensity occurred.

The work function of ZnO is related to a width of the space charge and band bending.⁴⁰⁻
⁴¹ The change of WF can point to the adsorption/desorption, interface forming and other changes on the surface. In our case, WF demonstrates that the band bending decreases when more Al₂O₃ layers are introduced in the nanolaminates what induced electron-rich area in ZnO. It is one of the factors which influences PL value.

In our previous works,^{1, 3} we observed similar results when no excitonic peaks were found for thin layers due to band bending and low grain size. This will result from the high concentration of defects, the low grain size (compatible with exciton Bohr radius for ZnO (2.6 nm)) and the surface band bending. Therefore, domination of defect level emission and low rate of exciton formation are observed.

The ZnO layers were polycrystalline with small grain size. We suppose that the grain boundaries will have the following effect in the optical properties of the nanolaminates: (i) Quantum confinement effect: due to the low grain size, the blue shift of the band gap is observed; (ii) Defects are formed on the grain boundaries;⁴² XPS showed the higher concentration of the defects for low ZnO thickness, what enhanced visible photoluminescence; and (iii) grain boundaries influence light absorption, particularly, the Urbach tail:⁴² a higher Urbach tail value is observed for low ZnO thickness due to the increasing of the grain boundaries active surface

(more defects). In the present study, we have shown that the ZnO work function significantly decreased with the decreasing of the bilayer thickness. We explain this observation by band bending. It is well-known fact that grain boundaries can induce localized energy states within the band gap leading to trapped, localized charges. These will form an electrostatic potential barrier – band bending, for the majority of carrier transport across grain boundaries and as well as enhanced recombination of photogenerated carriers, thus increasing the PL what we can observe on the PL spectra. Many other authors have shown that the formation of a nanocrystalline structure decreases the electron work function.⁴³⁻⁴⁴

CONCLUSION

Summarizing, the structural and optical properties of Al₂O₃/ZnO determined from the XPS, TEM, FTIR, XRD and PL analysis provide an important information about crystalline structure of nanolaminates on the 1D PAN substrate. The amorphous-to crystalline transition has been observed for ZnO nanolayers at the thickness of 2.6 nm on the 1D PAN nanotemplate. In particular, strong influence of the bilayer thicknesses on the crystallinity of ZnO nanolayers has been found. Due to the quantum confinement effect, the shift of XPS peaks to higher energies has been observed. Work function of Al₂O₃ was mostly independent on the bilayers number whereas the ZnO work function decreased with an increase of the bilayer number. The observed phenomenon indicate surface band bending on the upper layer of ZnO and further charge ‘screening’ by Al₂O₃ layers in internal ZnO layers of the nanolaminates.

Photoluminescence of the nanolaminates corresponded to emission bands in ZnO nanolayers. Due to low grain size, high defect concentration and surface band bending, no excitonic peaks were observed. The defect emission band was affected by the band bending and defect concentration. The observed XPS and PL data are in good correlation. The enhanced PL of the nanolaminates could be used for optical (bio)sensing.
