**Background** Multiple studies have evaluated the diagnostic and prognostic performance of conventional troponin (cTn) and high-sensitivity troponin (hs-cTn). We performed a collaborative meta-analysis comparing cTn and hs-cTn for diagnosis of acute myocardial infarction (AMI) and assessment of prognosis in patients with chest pain.

**Methods** MEDLINE/PubMed, Cochrane CENTRAL, and EMBASE were searched for studies assessing both cTn and hs-cTn in patients with chest pain. Study authors were contacted and many provided previously unpublished data.

**Results** From 17 included studies, there were 8,644 patients. Compared with baseline cTn, baseline hs-cTn had significantly greater sensitivity (0.884 vs 0.749, P < .001) and negative predictive value (NPV; 0.964 vs 0.935, P < .001), whereas specificity (0.816 vs 0.938, P < .001) and positive predictive value (0.558 vs 0.759, P < .001) were significantly reduced. Based on summary receiver operating characteristic curves, test performance for the diagnosis of AMI was not significantly different between baseline cTn and hs-cTn (0.90 [95% CI 0.85-0.95] vs 0.92 [95% CI 0.90-0.94]). In a subanalysis of 6 studies that alternatively defined AMI based on hs-cTn, cTn had lower sensitivity (0.666, P < .001) and NPV (0.906, P < .001). Elevation of baseline hs-cTn, but negative baseline cTn, was associated with increased risk of death or nonfatal myocardial infarction during follow-up (P < .001) compared with both negative.

**Conclusion** High-sensitivity troponin has significantly greater early sensitivity and NPV for the diagnosis of AMI at the cost of specificity and positive predictive value, which may enable early rule in/out of AMI in patients with chest pain. Baseline hs-cTn elevation in the setting of negative cTn is also associated with increased nonfatal myocardial infarction or death during follow-up.

More than 7 million patients present annually to the emergency department (ED) with chest pain, and >1 million patients are hospitalized each year in the United States with acute myocardial infarction (AMI). <sup>2</sup> The ability to rapidly exclude AMI through high-sensitivity troponin (hscTn) in combination with clinical evaluation may reduce ED length of stay, reduce financial cost, and improve outcomes in these challenging patients. Evidence suggests that even minimal elevations of conventional troponin (cTn) are associated with worse clinical outcome and that these patients may benefit from initiation of appropriate medical intervention.<sup>3,4</sup> Furthermore, use of a very low cut-point for hs-cTn has been suggested as a tool to rule out AMI due to the resulting high negative predictive value (NPV).5 However, the introduction of hs-cTn may significantly decrease specificity and can prompt a costly cardiovascular workup in patients in which cTn is elevated due to nonischemic causes for cTn release. Although multiple studies have compared the diagnostic and prognostic test characteristics of cTn and hs-cTn, the results of these data are mixed. Therefore, we performed a diagnostic and prognostic collaborative meta-analysis to assess cTn values and hs-cTn values in patients with chest pain.

#### **Methods**

#### Data sources and searches

Two independent reviewers (M.J.L. and N.C.B.) systematically searched (November 2013) Cochrane CENTRAL, EMBASE, and MEDLINE/PubMed for studies that assessed both cTn and hs-cTn in patients with nontraumatic chest pain. Search criteria included "high sensitivity troponin" AND ("chest pain" OR "acute coronary syndromes" [ACS] OR "myocardial infarction"). We limited our search to studies published in peer-reviewed journals; trials presented in abstract-only form were excluded. Our meta-analysis was performed in accordance with the Meta-Analysis Of Observational Studies in Epidemiology guidelines. 6 After obtaining full reports, eligibility was assessed from the fulltext articles with divergences resolved after consensus. No extramural funding was used to support this work. The authors are solely responsible for the design and conduct of this study, all study analyses, the drafting and editing of the manuscript, and its final contents.

#### Study selection

Prespecified inclusion and exclusion criteria were established at study onset. We included any study that (a) assessed patients with nontraumatic chest pain and (b) measured both cTn and hs-cTn levels. We excluded any study that (a) limited patients to only those with myocardial infarction (MI) or a specific subgroup of patients, (b) excluded patients with a baseline positive troponin, and (c) used a case-control format. We included studies regardless of whether patients with ST-segment elevation MI (STEMI) were included or excluded, whether the criterion standard diagnosis was made centrally or locally, and regardless of the cTn criteria used for diagnosis of AMI.

#### Data extraction and quality assessment

Data were abstracted by the same 2 investigators (M.J.L. and N.C.B.). An attempt was made to contact the corresponding authors of included studies to obtain complete data. Study quality was appraised in accordance with QUality Assessment of Diagnostic Accuracy Studies (OUADAS)-2. We accepted the authors' definitions of conventional and hs-cTn.

#### Data synthesis and analysis

Dichotomous variables are reported as proportions (percentages), whereas continuous variables are reported as mean (SD) or median. Sensitivity, specificity, positive predictive values (PPV), NPVs, positive and negative likelihood ratios (LRs), and diagnostic odds ratios (ORs) were computed. Pooling was performed using randomeffects methods. Measures of test performance are reported as point estimates (with 95% CIs). These were calculated for the baseline cTn at presentation, baseline hs-cTn at presentation, cTn at the second serial sampling (second cTn), and hs-cTn at the second serial sampling (second hscTn). Adjudication of AMI was typically defined by cTn. Given that authors used their own cut-points and delta changes in troponin with different times for sampling, we were unable to assess for value of serial sampling in this meta-analysis.

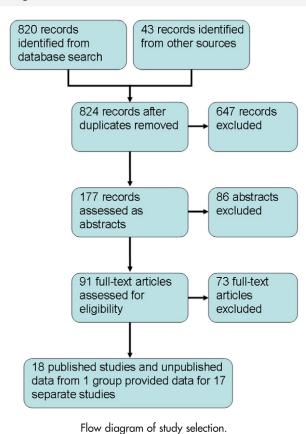

We generated weighted symmetric summary receiver operating characteristic (SROC) plots using the Moses-Shapiro-Littenberg method.<sup>8</sup> Area under the ROC curves of individual studies were pooled using a random effect generic-inverse variance method. Sources of clinical and statistical heterogeneity were explored by means of subgroup analyses and meta-regression with unrestricted maximum-likelihood meta-regression (inverse varianceweighted regression) on diagnostic ORs.

Binary outcomes from individual studies were combined with random-effect models, leading to computations of ORs with 95% CIs. Between-study statistical heterogeneity was assessed using the Cochran  $Q \chi^2$  test.  $I^2$  was calculated as a measure of statistical heterogeneity;  $I^2$  values of 25%, 50%, and 75% represented mild, moderate, and severe inconsistency, respectively. Small study or publication bias was explored with funnel plots and Peters test. 9 Statistical analysis was performed using Review Manager (RevMan) 5 version 5.1.7 freeware package (The Nordic Cochrane Centre, The Cochrane Collaboration, 2008, Copenhagen, Denmark), Meta-DiSc software, 10 and NCSS 2007 (Kaysville, UT), with statistical significance for hypothesis testing set at the .05 two-tailed level and for heterogeneity testing at the .10 two-tailed level.

#### Results

Of the 824 citations we identified, we assessed 177 abstracts from which we performed detailed review of 91

#### Figure 1

full-text manuscripts. Articles were excluded if the study was limited to only patients with stable coronary artery disease or only patients with ACS, patient duplication, exclusion of patients with baseline positive troponins, use of a casecontrol design, lack of or inadequate cTn data, and lack of adjudication data for AMI (excluded studies are listed in the supplement). Authors of the APACE study (Drs Twerenbold and Mueller) provided comprehensive data not only for the patients published in Haaf et al 11 but also on an additional 416 patients to provide the most updated data from their registry. Thus, our systematic review and collaborative metaanalysis comprises data from 18 published studies 12-29 (data from 3 studies were used to compile the findings of Aldous et al. 12-14) and updated data from the APACE study to provide comprehensive data on 17 studies. The details of our flow diagram can be found in Figure 1. Study characteristics are presented in Table I, and appraisal of diagnostic study quality Supplementary Table I. can be found i

The 17 studies included a total of 8,644 patients (median of 332 patients [range 58-1,818]). Patient characteristics are shown in Table II. The population had a weighted mean age of  $62\pm15$  years, 63% of patients were male, and there was a typical distribution of cardiovascular risk factors. Of the included patients, 20.7% were diagnosed as having AMI, with 5.2% admitted with STEMI. In studies that reported

unstable angina, 13.4% of patients were diagnosed as having unstable angina. Most studies used cTn levels for the adjudication of AMI, whereas several studies used a combination of cTn and hs-cTn levels Supplementary Table I).

Diagnostic performance of individual studies is summarized for baseline cTn and baseline hs-cTn

Supplementary Table II), along with the

second cTn and the second hs-cTn
Supplementary Table III). In addition to adjudicating AMI
with conventional cTn, 6 studies also performed separate
adjudication for AMI using the hs-cTn levels as the
criterion standard to define AMI, and diagnostic performance for baseline cTn and hs-cTn is provided (online
Supplementary Table IV). Finally, the area
under the ROC curves for baseline cTn, baseline hs-cTn,
second cTn, and second hs-cTn for diagnosis of AMI can
be found:
Supplementary Table V.

#### Diagnostic accuracy of cTn and hs-cTn

The assays used in each study are shown in Table I. As seen in Table III, baseline hs-cTn had significantly greater sensitivity (P < .001) and NPV (P < .001), and significantly lower negative LR (P < .01), whereas baseline cTn had significantly greater specificity (P < .001), PPV (P < .001), and positive LR (P < .01). The SROC curves suggest a trend toward better diagnostic accuracy with baseline hs-cTn (Table III, Figure 2). Comparison of pooled area under the ROC curves also suggested a trend toward better performance for baseline hs-cTn compared with baseline cTn (0.91 [95% CI 0.89-0.93] vs 0.89 [95% CI 0.86-0.91], respectively; P = .22,  $I^2 = 33\%$ ).

The second cTn was checked  $2.6 \pm 1.5$  hours after the baseline cTn, and the second hs-cTn was checked  $2.5 \pm 1.4$ hours after the baseline hs-cTn in 10 studies with 5,174 Supplementary Table III). These data demonstrated that the sensitivity remained significantly greater for the second hs-cTn compared with the second cTn (P < .05), whereas the second cTn had significantly greater specificity (P < .001), PPV (P < .001), and positive LR (P < .01) compared with the second hs-cTn (Table III). Summary receiver operating characteristic curves demonstrated no difference in diagnostic accuracy (Table III). Pooled area under the ROC curve was not significantly different between the second cTn and the second hs-cTn (0.95 [95% CI 0.93-0.97] vs 0.96 [95% CI 0.94-0.97], respectively; P = .42,  $I^2 = 0\%$ mentary Table V). Sensitivity analyses of conventional cTn or hs-cTn with exclusion of one study at a time did not appear to significantly change the sensitivity or specificity.

#### Meta-regression analysis

Meta-regression demonstrated that time from onset of chest pain to presentation was significantly associated with improved test performance for baseline cTn (regression coefficient  $0.61 \pm SE~0.20$ , P = .02) but not

baseline hs-cTn (regression coefficient  $0.38 \pm SE 0.20$ , P =

.10). Neither time from presentation to the second cTn

nor the second hs-cTn was significantly associated with

test performance. The percentage of patients with STEMI (regression coefficient  $-4.6 \pm 1.1$ , P = .001), male sex

(regression coefficient  $-8.3 \pm SE 3.0$ , P = .02), diabetes

(regression coefficient  $-8.0 \pm SE$  2.9, P = .02), and

prevalence of AMI (regression coefficient  $-3.2 \pm SE 1.2$ , P

= .02) were significantly associated with test perfor-

mance for baseline cTn but was not associated with test

performance for baseline hs-cTn. Age, creatinine levels,

and estimated glomerular filtration rate were not

associated with test performance for baseline cTn or

baseline hs-cTn. The definition of the delta, or the change

by rise and/or fall of troponin, used to diagnosis AMI was also not significantly associated with test performance.

95.503 (45.727-199.46)

in test performance for baseline cTnT and baseline cTnI

as assessed by pooled area under the ROC curves (0.89)

When limiting studies to those that provided a separate

adjudication using hs-cTn to define AMI, 12,14,16,17,24,27 (see

also APACE), the mean prevalence of AMI increased from

 $23\% \pm 15\%$  when AMI was defined by cTn to  $29.6\% \pm 16.5\%$ 

when AMI was defined by hs-cTn. When AMI was defined by

hs-cTn, the baseline hs-cTn had significantly greater test

performance based on pooled area under the ROC curves

compared with baseline cTn (0.91 [95% CI 0.88-0.94] vs 0.80

[95% CI 0.74-0.87], respectively; P = .004). Baseline cTn had

a significant reduction in sensitivity (0.666 vs 0.749, P <

.001) and NPV (0.906 vs 0.935, P < .001) when AMI was

defined by hs-cTn compared with when AMI was defined by

cTn. Baseline hs-cTn also had a significant reduction in

sensitivity (0.857 vs 0.884, P < .05) and NPV (0.953 vs 0.964,

[0.86-0.93] vs 0.91 [0.89-0.93], P = .30,  $I^2 = 7.1\%$ ).

#### **Discussion**

This systematic review and collaborative meta-analysis on 8,644 patients demonstrated that hs-cTn and cTn have excellent overall diagnostic accuracy for AMI in patients with chest pain. The hs-cTn assay has the benefit of a significantly greater sensitivity and NPV with a lower negative LR compared with cTn. However, this is at the cost of specificity, PPV, and positive LR. Meta-regression

analysis also suggested that time from onset of chest pain

to presentation was significantly associated with test

Heterogeneity:  $Tau^2 = 0.00$ ;  $Chi^2 = 5.66$ , df = 6 (P = .46);  $I^2 = 0\%$ 

Test for overall effect: Z = 8.97 (P < .00001)

test performance accuracy for baseline hs-cTn. These data validate previous works suggesting that hs-cTn can more accurately diagnose or exclude AMI early after chest pain. The Prevalence of AMI, STEMI, diabetes mellitus, and male sex also was associated with test performance for baseline cTn but not baseline hs-cTn. When AMI adjudication is performed with hs-cTn as the criterion standard to define AMI, baseline hs-cTn had better test performance as assessed by pooled area under

performance for baseline cTn but was not associated with

10

100

the ROC curve compared with baseline cTn. Elevation of baseline hs-cTn identified a greater number of patients who died or had nonfatal MI during follow-up compared with elevation of baseline cTn. Finally, these data demonstrate that baseline elevation of hs-cTn but a negative baseline cTn was associated with an incremental increase in risk for death or nonfatal MI during follow-up. Although troponin assays have previously been compared in meta-analysis, <sup>33</sup> our meta-analysis is the first to focus specifically on diagnostic and prognostic role of hs-cTn and conventional cTn and performed meta-regression to assess the affect of different variables on diagnostic accuracy. These data support a

The development of a universal definition for AMI<sup>34</sup> has

greatly aided the field of cardiology by providing a means to reliably compare diagnostic tests and therapies.

broader acceptance of hs-cTn.

biomarker result.

Likewise, establishment of standards for cardiac troponins and adoption of common cut-points 30,31,35,36 may not only enable improved comparison between assays but also help provide uniform data that physicians can more readily and confidently apply to clinical practice. Adoption of hs-cTn into the ED evaluation of chest pain may significantly alter current practice. Although hs-cTn may enable rapid rule out of patients who present to the ED with chest pain, 32,37 concern exists that the reduction in PPV and specificity may lead to more extensive cardiovascular testing. Although minimal elevations in hs-cTn may not necessarily identify AMI, it is important to recognize that these patients are at increased risk for adverse outcomes and should receive appropriate medical intervention. 4 Finally, it is also critical to interpret these biomarkers in the clinical context of the patient. The importance of clinical history and appropriate electrocardiographic evaluation cannot be underestimated. For example, the diagnostic value of a negative troponin is less helpful if the patient's presentation is consistent with unstable angina because the clinical presentation will guide management rather than the

enable appropriate comparison of cTn and hs-cTn in a "realworld" scenario, we excluded studies in which patients were limited to those with a baseline negative troponin because this inherently introduces bias. Similarly, we excluded studies that were limited to only patients with ACS or specific populations. We did not exclude studies with STEMI patients, although this is an electrocardiographic and clinical diagnosis, as we wished to assess the diagnostic accuracy of the assays in all patients with chest pain. The relatively high incidence of AMI in our population does lead to a bias in the PPV of the test, which is important to acknowledge. However, positive and negative LR should not be influenced by this bias. Other limitations are those inherent to meta-analyses, which include lack of raw or uniform data, and use of different troponin assays and cutpoints. We were also unable to adjust the diagnosis of AMI based on the delta for the rise and/or fall of troponin and the

This meta-analysis has several important limitations. To

use of longer follow-up may admix events related to ACS with those related to the predictive value of cTn detected in the absence of ACS. Although a random-effect pooling method adjusts for it, another limitation of this meta-analysis is the heterogeneity observed among studies, although this appeared to be low. Finally, meta-regression techniques are limited given the lack of raw patient information and should therefore be viewed with caution and as hypothesis generating.

In conclusion, both cTn and hs-cTn have excellent diagnostic accuracy, but our data support broader use of hs-cTn given the improvements provided in sensitivity, NPV, and identification of patients at risk for adverse outcomes during follow-up.
