14 Anthracotheres dispersed from Asia toward Africa at least three times: at the
15 Eocene/Oligocene transition, during early Miocene and later during the Miocene.
16 Those dispersals are important datum events for African tertiary biochronology.
17
18 New fossil remains of early *Libycosaurus*, the genus implicated in the Late
19 Miocene dispersal, are described from a new Tunisian locality of the Kasserine
20 area. The new fossils enhance the hypodigm of *Libycosaurus algeriensis* and
21 permit increased resolution of the phylogenetic position of this species using
22 cladistics analysis. The inclusion of the genus *Libycosaurus* within the well-
23 described *Merycopotamus* lineage allows us to constrain its dispersal time.
24
25 Dispersal of this anthracothere from the Indian sub-continent to Africa was
26 probably facilitated by sea level decrease during the early Tortonian, just
27 preceding the *Hipparion* dispersal event. This new age estimation refines the
28 resolution of the succession of late Miocene deposits in the Maghreb and frames
29 the date of the onset of the Sahara.

Introduction

Anthracotheres are an extinct family of morphologically and ecologically diverse cetartiodactyls, usually interpreted as swampy environment inhabitants. Within the superfamily Hippopotamoidea, the anthracotheres are considered closely related to the Hippopotamidae (e.g., Boisserie et al. 2011; Lihoreau, Boisserie, et al. 2015), but parts of the branching sequence within this clade are still unclear; as such the content of some anthracothere genera requires revisions. Anthracotheres are also particularly remarkable as they display unusual dispersal abilities, leading several palaeontologists to regard them as ‘ungulate pioneers’ in most of the intercontinental dispersal events (e.g., Ducrocq 1995; Lihoreau and Ducrocq 2007; Holroyd et al. 2010; Grandi and Bona 2017; Scherler et al. 2018).

The last African genus of anthracotheres, *Libycosaurus*, engaged in a form of semi-aquatic-lifestyle as indicated by the marked specialisation of its skeleton and its paleobiology (Lihoreau et al. 2006; Lihoreau et al. 2014). During the middle-late Miocene in Africa, *Libycosaurus* underwent a spectacular evolution characterized by a substantial body size change and a diet shifting (increase in C4-plant consumption), associated with social modifications notably with sexual size dimorphism and indices of fight between males (Lihoreau et al. 2014). This evolution was linked to the reduction of *Libycosaurus* habitat through change of the river system probably due to the variation of Sahara expansion. However, the evolutionary history of the genus is incomplete, as the origin of the genus remains unclear. A recent validation of the small and plesiomorphic species *Libycosaurus algeriensis* Ducrocq et al. 2001, with new material from the locality of Bir el Ater 3 (Algeria), highlighted the possibility that *Libycosaurus*

1
2 originated in Africa during the middle Miocene following the arrival of its ancestor
3 from the Indian subcontinent (Lihoreau, Hautier, et al. 2015).
4
5

6 We recently discovered new fossils attributable to *Libycosaurus algeriensis* in
7 Tunisia, from Sidi Hedri, a new locality situated near the town of Kasserine. We
8 describe here this new fossil material, which provides previously unknown elements for
9 documenting the basal morphotype of the genus. We perform a cladistic assessment
10 incorporating these new data with previously known morphological evidence, in order
11 to formalize the position of *Libycosaurus* within the anthracotheres. The original
12 phylogeny discussed in this study constrains a paleobiogeographic scenario prior to the
13 initiation of the Sahara desert and contemporaneous to a major sea-level drop. This
14 scenario refines the age estimates of some North African vertebrate fossil-bearing
15 deposits of the Miocene epoch.

Materials and Methods

Provenance of the new fossil material

The new material was discovered in the western part of central Tunisia, in the Kasserine region, north of the Djebel Chambi (Fig. 1). The locality yielded three specimens belonging to the same taxon, due to coherence in size and morphology. The new remains consist of a right upper canine (SHI01), a right lower mandible with P/3-M/2 (SHI02) and a left M/3 (SHI03). These fossils were found during our 2012 field expedition and come from a unique locality, Sidi Hedri, corresponding to a limited spot and horizon (F4 on Fig. 1). The name locality is due to its proximity to the Marabout of Sidi Hedri. The material is housed in the paleontological collections of the Museum of the Office National des Mines (ONM) in Tunis, Tunisia.

17 *Stratigraphical context*

18

19 The new Sidi Hedri fossil-bearing locality is situated in the Bir-Om-Ali stratigraphic
20 section (Fig. 1; Vialle et al. 2013; Sweydan et al. 2018), north side of the Djebel
21 Chambi. This section overlies laterally the late early to early middle Eocene fossil-
22 bearing localities of Chambi locus 1 (CBI-1) and Chambi locus 2 (CBI-2), which have
23 yielded numerous fossil remains of key taxa documenting the early evolutionary history
24 of several vertebrates from Africa (e.g., Marivaux et al. 2015, Ravel et al. 2016,
25 Mourer-chauviré et al. 2016, Tabuce 2018). The section contains the late Eocene
26 locality of Bir-Om-Ali that yielded fragmentary fossil remains of the embrithopod
27 *Arsinoitherium* (Vialle et al. 2013; F2 on Fig. 1), the fossiliferous locality of Mabrouk, a
28 level with reworked marine fossils dated from the late Eocene-early Oligocene
29 (Sweydan et al. 2018; F3 on Fig. 1), and a Neogene fine grained sandstone
30 corresponding to the Sidi Hedri locality (F4 on Fig. 1). The Sidi Hedri fossiliferous
31 horizon overlies alluvial-fan conglomerates in a unit consisting of fluvio-deltaic
32 deposits. This unit was generally considered as belonging to the Beglia Formation (Fm.)
33 but the definition of this formation might be taken with caution (e.g., Mannaï-Tayech
34 2006; Mannaï-Tayech 2009; Belghithi et al. 2016). The sandstone attributed by
35 Hartenberger et al. (2001) to the Beglia Fm. in fact corresponds to the uppermost
36 Paleogene levels where the Mabrouk locality occurs (Sweydan et al. 2018). The

1
2 geological study made by Hartenberger *et al.* (2001) did not include the area where the
3 Neogene sediments outcrop. Furthermore, recent discussion of the Miocene sandstones
4 capping the Nementcha Fm. in Algeria (Lihoreau, Hautier, et al. 2015), only 130 km
5 southwest of Sidi Hedri, highlighted the critical role of fossil assemblage in correlating
6 between continental formations, and demonstrates that it is best to avoid using only
7 facies correlation for precise dating.
8
9

10 The Neogene deposits in Tunisia unconformably overlie the latest Paleogene
11 deposits (Swezey 2009). The Neogene sandstones resulted from fluvial system
12 deposits in deltaic context over a long period of time, ranging from the Serravalian up to
13 the late Tortonian (Belghithi et al. 2016). They are usually gathered in formations
14 (Beglia Fm., Saouaf Fm., and Segui Fm.), but the variety of facies and the progradation
15 of the system make lithostratigraphy unreliable at a regional scale. In Tunisia, the
16 Neogene deposits yield two important fossil vertebrate faunas that provide constraints
17 on the age and chronology of associated formations. First, the locality of Bled Douarah
18 (Beglia Fm, western Tunisia) is assigned to the late Serravalian-early Tortonian in age
19 (Werdelin 2010). Bled Douarah is divided into two sedimentological units, likely
20 corresponding to different environmental deposits and possibly climates (Mannaï-
21 Tayech 2009). The faunal assemblages in each unit differ. Only the upper unit has
22 yielded equids (Robinson and Black 1969; Robinson and Black 1974) and seems to
23 represent more forested and more humid conditions (Mannaï-Tayech 2009). The arrival
24 of equids in Africa is estimated close to 10.5 Ma (early Tortonian; Bernor et al. 2010).
25 Using the equid biotic marker, the earliest deposits referred to the Beglia Fm. are
26 estimated to document deposits dating near the Serravalian/Tortonian transition (Biely
27 et al. 1972; Mannaï-Tayech 2009; following Hilgen et al. 2012), or near the beginning
28 of the marine regression recorded during the earliest Serravalian (13.8 Ma following

Hilgen et al. 2012; Belghithi et al. 2016). Recently, a part of the Beglia Fm. in western Tunisia was correlated to the Saouaf Fm. in eastern Tunisia (Mannaï-Tayech 2009; Belghithi et al. 2016). The second fossil vertebrate fauna is from the Djebel Khechrem El Artsouma (Geraads 1989) and belongs to the Segui Fm., stratigraphically overlying the Beglia Fm. (Mannaï-Tayech 2009; Belghithi et al. 2016). This locality is estimated to be 0.5 to 1 myr more recent than the fauna from Bled Douarah (Geraads 1989). Several other localities from the Neogene silicoclastic deposits of Tunisia are known but cannot be precisely dated due to the scarcity of the material or poorly time constrained taxa (e.g., (Mannaï-Tayech and Otero 2005)).

Anatomy and cladistics analyses

The teeth description follows the dental nomenclature established for Hippopotamoidea (Boisserie et al. 2010). Tooth measurements follow Lihoreau *et al.* (2014). A calculation of the flattening index (fli) of the canine follows Kostopoulos *et al.* (2012), which consists of a ratio at the cervix between the mesio-distal length and the labio-lingual length ($L_{md}/L_{ll} \times 100$).

We consider the new fossil material described here as *Libycosaurus algeriensis*, a species previously described in Algeria (Ducrocq et al. 2001; Lihoreau, Hautier, et al. 2015). Some of this material complements the hypodigm of this species. The new material betters our knowledge of *L. algeriensis*, and facilitates inclusion of *L. algeriensis* into a phylogenetic matrix incorporating recent matrices assembled for deciphering internal phylogenetic relationships among taxa of the superfamily Hippopotamoidea (including the “Anthracotheriidae” and the Hippopotamidae). Here, we use the latest character matrices dealing with Merycopotamini (Lihoreau et al. 2016) and with Hippopotaminae (Boisserie et al. 2017), as well as some updates (supp. data).

We added recent data for the species *Bothriogenys andrewsi* Schmidt, 1913, for which new material was recently published (Sileem et al. 2015), leading to better character scoring for *Bo. andrewsi* compared to previous analyses (Lihoreau, Boisserie, et al. 2015). Then, we added four new characters that deal with the morphological conditions describing the genus *Libycosaurus* with respect to the other genera. We coded, on lower molars, the morphology of the postentocristid (= entoconid fold, 63, supp. data) and the pattern of incomplete hypoconulid (80, supp. data); on upper molars, the relation between the mesostyle and cingulum (139, supp. data); and on the mandible, the presence and morphology of a notch (156, supp. data). We also added the position of the main palatine foramen, a diagnostic character in *Merycopotamus* species (162; Lihoreau et al. 2004; character already used in Boisserie et al. 2005). All characters are unordered and unweighted. Parsimony analyses were performed on the new matrix (64 taxa and 181 characters) with PAUP 4.0a164 (Swofford 2002) using heuristic searches with random step-wise addition (1000 replications with randomized input order of taxa) and tree-bisection-reconnection branch swapping options. We calculated the Bremer support for each node up to five supplementary steps.

14
15

16
17 *Differential diagnosis.* *Libycosaurus algeriensis* differs from other species of the genus
18 (*L. anisae* and *L. bahri*) in its smaller dimensions with shallow mandible, the presence a
19 small endometacristid on lower molars, the ectocristylids frequently developed in
20 cusplets in the transverse valleys, which is rare in other species, the large lingual
21 cingulum around the protocone of upper molars (even in worn specimens), and in the
22 preprotocristid on p/4, which is directed mesially then lingually as in most
23 Merycopotamini and unlike in the two other species of *Libycosaurus*. It also differs
24 from *L. anisae* in the presence of only one entostyliid on the third lobe of the M/3. It also
25 differs from *L. bahri* in the presence of a posthypocristulid on M/3, the retention of a
26 weak vascular impression on the mandible, and in the presence of large and blurry
27 Hunter Schreger Bands on the tooth enamel.

Comparative descriptions

45
46 *Upper canine (SHI01).* The crown apex is broken but wear facet and crown section are
47 visible (Fig. 2). The cervix section is tear-shaped with a sharp distal keel, a swollen
48 labial border and a flatter lingual border. The mesial border is rounded and bears the
49 worn part of the tooth. The enamel appears thin and finely wrinkled. The whole tooth
50 (crown plus root) is slightly inclined outward. The root is covered by cement, displays
51 at least three constrictions toward the root apex, and remains open at its apex.
52
53
54
55
56
57
58
59
60

Considering the canine morphology and the enamel ornamentation, both gathered conditions expected for a bothriodontine anthracothere. In *Bothriodon velaunum* Cuvier, 1824, an early Oligocene bothriodontine, the upper canine of males exhibits a clear demarcation at the cervix, with a smaller crown. On SHI01, the crown appears to be in continuity with the root. The SHI01 canine has a similar morphology of transverse section to that of *Elomeryx*, another Oligocene bothriodontine, but differs in being more transversally compressed (Flattening index = 53.6% in *E. borbonicus* (Geais, 1934; see Kostopoulos et al. 2012) and 60.9% in SHI01). SHI01 is larger than *E. borbonicus* and lacks the serration on the distal keel that is visible on the canine of *E. borbonicus*.

Upper canines are known in few merycopotamine species. *Afromeryx zelteni* Pickford, 1991b, a stem Merycopotamini, displays a round and smaller upper canine section at the cervix (M82211). *Merycopotamus medioximus* Lihoreau et al., 2004, shows a canine of comparable dimension (Table 1, Fig. 2), with a similar wrinkled enamel characterized by longitudinal striations, and equivalent crown height proportion (NG104; Lihoreau et al. 2004). The labial border seems to be more swollen than in SHI01. There is a keel running on the distal border of the tooth, and a slight one is visible on the mesial border. In *Merycopotamus dissimilis* (Falconer and Cautley, 1836), the canine section is larger (Fig. 2), subcircular with slight distal and mesial keels in the three known specimens (Y49776, M16551, and M16552). The enamel covers at one third of the total length of the tooth. The root is closed and covered with cement in the only specimen where it is observable (Y49776; Lihoreau et al. 2007). Indeed, despite the marked similarities with the canine of *M. medioximus*, the SHI01 canine also shares anatomical traits with the canines of the two other species of *Libycosaurus* (*L. anisae* and *L. bahri*), notably in the lack of mesial keel, the presence of a lingual flattening of the crown section at the cervix, an open root apex, and in the presence of longitudinal

1
2
3 grooves both on the labial and lingual sides of the root, which are not marked in canines
4 of *Merycopotamus* (Pickford 2006; Lihoreau et al. 2014). The SHI01 canine has smaller
5 dimensions at cervix than the upper canine of *L. anisae* (Black 1972; Pickford 2006)
6 and that of *L. bahri* (Lihoreau et al. 2014; Fig. 2D; Table 1). It is also more curved. A
7 similar small radius of curvature occurs in upper canines of *Merycopotamus*.
8
9
10
11
12
13
14
15
16

17 *Lower premolars (P/3-4 on SHI02)*. The premolars are narrow and dominated by a
18 salient protoconid, which occupies a labial position (Fig. 3-4). A short and trenchant
19 preprotocristid joins the mesio-lingual margin of the tooth. It is adorned with three
20 successive small cusplets that decrease in height before reaching the mesial cingulid
21 (Fig. 3A-B, Fig. 4A). Such an unusual cusplets organization/striation is typical of
22 Merycopotamini, but such an amount of accessory cusps on P/3 and P/4 is only
23 known in species of *Libycosaurus* (Fig 4B-C) and in *Hemimeryx blanfordi* Lydekker,
24 1883 (Lihoreau et al. 2016; Fig. 4). The preprotocristid on P/4 has a mesial orientation
25 near the protoconid apex and turns abruptly distally, a pattern proposed as a features of
26 the Merycopotamini (Lihoreau et al. 2016; Fig. 4). This structure is less marked in the
27 latest known Merycopotamini, such as *L. anisae* and *L. bahri*, and in *M. dissimilis* (Fig.
28 4B-C, F). The postprotocristid is slightly arched and has a lingual position with respect
29 to the protoconid, also a Merycopotamini trait. The postprotocristid reaches a hypoconid
30 and then the distal cingulid in a small distostylyl (Fig. 4). An endoprotocristid emerges
31 from the postprotocristid and reaches an entostylyl (larger on P/4 than on P/3). The
32 premolars are narrower than those of *L. anisae* and *L. bahri* (Table 1), and equal the size
33 of *Merycopotamus nanus* Falconer, 1868 and *Sivameryx* spp. The P/4 seems slightly
34 smaller than the only known P/4 of *L. algeriensis* (Ducrocq et al. 2001). The mandibular

8
9

10 *Lower molar.* Unfortunately, the right lower molars M/1-2 preserved on SHI02 are
11 worn and badly preserved. The M/1 is similar in size to that of *Sivameryx* and
12 *Merycopotamus* spp. (Table 1). The left M/3 is well preserved (SHI03; Fig. 5) and
13 displays a bothriodontine pattern, which is characterized by an important development
14 of the cristids, notably the long prehypocristid that reaches the lingual margin of the
15 tooth. It also exhibits some Merycopotamini characters such as the lack of connection
16 between the premeta- and preprotocristids, and the pinched loop-like hypoconulid
17 (Lihoreau et al. 2016). Furthermore, the SHI03 M/3 lacks the premetacristid, displays a
18 pinched postentocristid between the entoconid and the posthypocristid, and a notched
19 posthypocristulid (an incomplete loop-like hypoconulid), all of which are diagnostic
20 traits of *Libycosaurus* (Lihoreau, Hautier, et al. 2015). Mesial to the posthypocristulid
21 notch, there is a marked postentostylid. This pattern is observed in all known specimens
22 of *L. algeriensis* and some *M. medioximus*. However, it differs from that characterizing
23 M/3 of *L. anisae* where there are many stylids without a clear groove separating the
24 entostylid from the rest of the posthypocristulid, and from that of *L. bahri*, where the
25 tooth lacks the posthypocristulid (Lihoreau, Hautier, et al. 2015). Lingual cusps of
26 lower molar are more linguo-labially flattened in *L. algeriensis*, whereas they present a
27 rounded outline (in occlusal view) in other species of *Libycosaurus*. This is probably
28 due to development of sharper cristids in *L. algeriensis* than in the other species. This
29 condition also exists in early species of *Merycopotamus*.

Compared to *L. anisae* and *L. bahri*, the M/3 (SHI03) shows a blurry
endometacristid, not as developed as in *Sivameryx*, but similar to that observed in some

specimens of *Merycopotamus*. Such a very small endometacristid is observed in material of *L. algeriensis* from Algeria (Lihoreau, Hautier, et al. 2015).

There is a cusplet within the transverse valley that could be considered as an inflated ectocristilid as it joins the labial cingulid, forming small ectostyliid. This pattern is known in most of specimens of *L. algeriensis* (6 of the 7 known lower molars). We also observed this structure within Merycopotamini, notably in some specimens of *M. nanus* (almost 4 of 15 molars) and in *Sivameryx* (close to 5 on 11 molars). In contrast, the ectocristilid in *L. anisae* and *L. bahri* do not form a cusplet (or rarely: 0 and 1 on at least 23 and 40 lower molars, respectively) but form an alignment of the enamel knob instead. The SHI03 M/3 is similar in size to the specimens from Bir el Ater 2 and 3 (UONM10, 9 and 14; Fig. 5; Lihoreau, Hautier, et al. 2015) and also very close to the mean value of *M. medioximus* (Table 1).

Phylogeny

Heuristic searches have yielded 18 equally most parsimonious trees of 1226 steps each (CI= 0.30; RI= 0.64). A strict consensus tree is provided in Figure 6. The phylogenetic relationships are particularly well resolved, despite an apparent important number of homoplasies. The latter are much involved in the structure of the tree. The observed polytomies concern relationships between the two *Kenyapotamus* species and the Hippopotaminae, between *Sivameryx* spp. and *Hemimeryx*, and within the clade *Brachydodus* spp. + *Bothriogenys andrewsi*. The latter is mainly due to the small number of characters scored for *Bo. andrewsi* (few known fossil remains) and uncertainties regarding *Brachydodus*, suggesting a need for a revision of its evolutionary history. However, this study proposes *Bo. andrewsi* as a basal member of the *Brachydodus* clade, thereby representing the only Paleogene representative of that clade (this would suggest

a generic re-attribution of the species *Bo. andrewsi*; i.e. *Brachyodus andrewsi* following Schmidt 1913). Our phylogenetic analyses, based on the characters used here (Lihoreau et al. 2016), fail to discriminate the genus *Sivameryx* from *Hemimeryx*. The two genera are considered phylogenetically close and differ mainly by their upper molar morphologies notably the dimension of the paraconule (Lihoreau et al. 2016). In the resulting tree the paraconule reduction appears as a reversion in *Sivameryx*. Further phylogenetic analysis should therefore add more *Sivameryx* species to discuss this particular point. Unfortunately, new material of *Sivameryx moneyi* (Fourtau, 1918) from Wadi Moghra (Miller et al. 2014) cannot be included in this cladistic analysis due to the lack of published description for the upper tooth. It is worth noting here that one specimen of *S. moneyi* (CUWM 172) displays five upper premolars (Miller et al. 2014) as in all the specimens of the two well-known species of *Libycosaurus* (Lihoreau et al. 2006; Pickford 2006). Therefore, unlike what is proposed by Miller et al. (2014, p.974), this is not ‘a fairly common occurrence among anthracothere species in general’, and should hence be tested in order to decipher possible close affinities between *S. moneyi* and *Libycosaurus*.

The main clades depicted from this analysis, which display Bremer indices (BI) of 3 or more (Fig. 6), are those of the suines, anthracotheriines, hippopotamids + *Epirigenys lokonensis* Lihoreau, Boisserie, et al., 2105, hippopotamids, hippopotamins, bothriodontines, *Brachyodus* spp. + *Bo. andrewsi* and merycopotamins (Fig. 6). The main aim of this analysis was to assess the phylogenetic position of *L. algeriensis* within the Merycopotamini. Therefore, we will here focus primarily on the description of the nodes that gather the species of *Merycopotamus* and those of *Libycosaurus*.

First, the *Merycopotamus+Libycosaurus* clade (BI=5) is characterized by nine non-ambiguous traits: the presence of a groove on the labial side on the lower canine

(12¹), also observed in Suina, the lack of ectometafossid on lower molars (54¹), a character convergent with some Bothriodontinae and Hippopotaminae, an important regression or lack of the endometacristid on lower molars (55⁰), which is convergent with the Hippopotamidae, *Brachyodus* (+*Bo. andrewsi*) and stem Hippopotamoidea, the lack of premetafossid on lower molars (57¹), convergent with *Brachyodus*, *E. borbonicus* and *Myaingtherium*, a reduced postectoentocristid (60¹), which appears as a reversion in Hippopotamoidea, a convex mesial border of P4/ (105¹), also observed in some Bothriodontinae (*Bothriodon*, *Aepinacodon* and *S. africanus* (Andrews, 1914), the lack of postectoprotocrista (114⁰), as in Hippopotaminae, some microbunodontines and *Siamotherium*, a maximal thickness in the middle of the sagittal section of the symphysis (153⁰), as in Hippopotamidae and *Anthracotherium*, and the presence of a mandibular notch with a short extension below m/3 (156²), as observed in *E. borbonicus*.

Merycopotamus nanus is the sister-taxon of a clade including the other species of *Merycopotamus* (successively arranged) and the three species of *Libycosaurus*, the latter forming a subclade. This *Merycopotamus*- *Libycosaurus* clade is supported (BI= 5) by six non ambiguous traits: crown of the male lower canine with a prolonged growth (15²), also known in Hippopotamidae and Suina, the presence of a postentocristilid on P/4 (42¹), convergent with Hippopotamidae, *Elomeryx* spp., *S. palaeindicus* and *Microbunodon minimum* (Cuvier, 1822) upper canine with prolonged growth of the root (86²), convergent with Suina, a partial to total division of the mesostyle on upper molars (140¹), also observed in *Bothriodon*, *Aepinacodon* and *Elomeryx borbonicus*, a bony fusion of the mandibular symphysis in adult (152¹), a character highly convergent within Hippopotamoidea but characteristic of several Merycopotamini, and the presence

1
2
3 of an inner radial enamel (schmelzmuster with 3 layers, 164¹), which is highly
4
5 convergent within Hippopotamoidea.
6
7

8 *Merycopotamus dissimilis* and the three species of *Libycosaurus* form a well-
9 supported clade (BI=5) characterized by six non-ambiguous traits, including a non-
10 homoplastic apomorphy of the Hippopotamoidea. This exclusive trait is the presence of
11 an ectometacristule developed on the last upper molars (not M1/; 118²). This character
12 differs from the condition observed in other Hippopotamoidea where the
13 ectometacristule is expressed on M1/ and also from other Merycopotamini where the
14 ectometacristule is absent. The other unambiguous traits are the presence of a
15 postentocristid (62¹), which is also observed in some *Bothriogenys*, Hippopotamidae,
16 Anthracotheriinae, although this postentocristid is mesio-distally oriented between the
17 posthypocristid and the entoconid (= the entoconid fold in Lihoreau et al. 2007) and
18 only observed in *S. africanus* among the Hippopotamoidea (63¹), the presence of an
19 ectostyliid on lower molars (72²), also known in Hippopotamidae and stem
20 Hippopotamidae, in *E. borbonicus*, *S. africanus* and in *H. blanfordi*, an incomplete
21 posthypocristulid (79¹), also known in *Afromeryx zelteni* and *Chororatherium*, the
22 rostral opening of the main palatal foramen (162²), which is a character convergent with
23 Hippopotamidae and *B. onoideus* (Gervais, 1848-52).
24
25

26 The three species of *Libycosaurus* are gathered together (BI= 4) on the basis of
27 four non-ambiguous traits including two non-homoplastic apomorphies: the presence of
28 at least two accessory cusplets on the preprotocristid of all lower premolars (18²) and a
29 long postentocristilid on P/4 that reaches the distal cingulid (42²). Both character states
30 are derived condition of what is known in Merycopotamini (18¹) or *Merycopotamus*
31 (42¹). The other two non-ambiguous traits are the endoprotofossilid on P/4 that reaches
32 the lingual cingulid wall (ectocristilid; 41¹), a character which is convergent with *E.*
33
34

borbonicus, *A. zelteni* and *S. africanus* within the Bothriodontinae, and that is linked to the important development of the ectocristilid (42¹⁻²), and finally the cingulum reduction at the mesostyle (139²), which is convergent with *Brachyodus* spp., *Bothriogenys fraasi* (Schmidt, 1913) and *Bo. andrewsi*, Hippopotamidae, *Bothriodon*, *Aepinacodon* and *Hemimeryx*.

In our cladistic analysis, *Libycosaurus algeriensis* forms the earliest offshoot of the *Libycosaurus* lineage, appearing as the sister-taxon of the two other species of the genus (*L. anisae* and *L. bahri*). The latter clade shows two non-ambiguous traits, including one non homoplastic synapomorphy: the preprotocristid direction on P/4 is lingual and then mesial (43¹), whereas it is mesial then lingual in other Merycopotamini. The other non-ambiguous trait is the lack (loss) of the mandibular notch, mesial to the vertical ramus (156⁰), which is convergent with *Afromeryx* and the Hippopotaminae.

Discussion

The age of Tunisian silicoclastic formations

The new anthracothere fossil remains from Sidi Hedri are the first known for the species *Libycosaurus algeriensis* in Tunisia. Based on the determination of these fossils, we can postulate that the sedimentary deposits where these fossils were found, are most likely contemporaneous with the Nementcha Fm. in Algeria, inasmuch as *Libycosaurus algeriensis* was originally described from that rock unit (Fig. 1; Ducrocq et al. 2001; Mahboubi et al. 2003; Lihoreau, Hautier, et al. 2015). *Libycosaurus algeriensis* does not display some of the derived morphological traits characterizing *L. anisae* and *L. bahri*, and has so far never been found in association with those species. Evolutionary trends observed in the genus, notably general size increase and reduction of molar crests

suggest that *L. algeriensis* represents the most primitive known species of the genus (Lihoreau, Hautier, et al. 2015). This suggests an earlier origin for *Libycosaurus*. This view is corroborated here by the results of our phylogenetic analysis, which included more characters and a better scoring of the matrix for some taxa, notably *L. algeriensis*. Indeed, *L. algeriensis* was previously known only by 14 elements (upper molars, lower molars, a fragmentary mandible, and a lower P/4 (Ducrocq et al. 2001; Lihoreau, Hautier, et al. 2015). The new material has substantially improved the hypodigm of the earliest species of *Libycosaurus*, and thus permitted to assess its phylogenetic relationships. The phylogenetic results presented here recover the monophyly of the *Libycosaurus* genus with *L. algeriensis* falling as the sister of *L. anisae* and *L. bahri* (more recent species). The *Libycosaurus* clade is nested within a paraphyletic *Merycopotamus* clade. The morphological characters in support of the *Libycosaurus* clade (e.g., accessory cusplets on lower premolars) were already included in the amended diagnosis of the genus (Lihoreau et al. 2014). Thanks to the new fossil material and based on the phylogenetic results, we could add some aspects of the morphology of the P/4 (e.g., long ectocristilid including the distal development of the endoprotostyloid) and of the upper molars (cingulum reduction at mesostyle) to the genus diagnosis.

A key point of this discovery is the identification of two diachronous species of *Libycosaurus* (*L. algeriensis* and *L. anisae*) in similar facies of siliciclastic deposits, which were previously combined as Beglia Fm. We propose that either (1) that different formations of late middle to early late Miocene sandstones were deposited in Tunisia and therefore that all ochre sandstones should not be considered by default as documenting (belonging to) the Beglia Fm., or (2) that the Beglia Fm. records deposits

1
2 corresponding to a long period of time, which require that they be separated into
3 different ages.
4
5

6 Within the Beglia Fm., the locality of Bled Douarah (including two levels) was
7 dated around 10.5 Ma (arrival in Africa of hipparions following Bernor et al. 2010). The
8 *Libycosaurus* from both levels do not show morphological discrimination (Black 1972)
9 or biometrical difference (Fig. 5). Therefore, this material may documents one unique
10 species, *L. anisae*, documenting a similar evolutionary grade. Thus, these two levels
11 might not represent a long time-span. The base of the Beglia Fm. may be early
12 Tortonian (11.6 Ma; Hilgen et al. 2012) or recording the earliest sediments
13 corresponding to the onset of the Serravalian marine regression (13.8 Ma; Hilgen et al.
14 2012). We can add here that the Beglia Fm. corresponds to a long regressive sequence,
15 and that the sediments characterizing the Sidi Hedri locality are also within regressive
16 deposits, and furthermore are older than the Bled Douarah low level.
17
18

19 Another important point is that the *Libycosaurus* clade shares a common
20 ancestry with *Merycopotamus dissimilis* and might originate from a *M. medioximus*-like
21 ancestral stock (Fig. 6). *Merycopotamus medioximus* is known from 10.4 Ma to 8.6 Ma
22 in deposits recorded in the Potwar Plateau (Pakistan; Fig. 7; Lihoreau et al. 2007). The
23 latter area displays successive species of *Merycopotamus*, thereby suggesting a possible
24 anagenetic lineage in this case. Some transitional form between *M. nanus* and *M.*
25
26 *medioximus* are present between 11.3 and 10.5 Ma. Therefore, a possible age for
27
28 *Libycosaurus algeriensis* could be bracketed between the earliest *M. medioximus*-like
29 ancestral stock (11.3 Ma) and the earliest level of Bled Douarah (older than 10.5 Ma).

The impact of the Tortonian/Serravalian marine regression on Libycosaurus dispersal

The phylogenetic and geographic origins of *Libycosaurus* are deduced from results of the cladistics analysis (Fig. 6). Although *Libycosaurus* was proposed as sister-taxon of the *Merycopotamus* clade in previous analyses (Lihoreau et al. 2006; Lihoreau et al. 2014), *Libycosaurus* was supposed to originate from a *M. nanus*-like ancestral stock from Asia (Lihoreau et al. 2014). From the phylogenetic results presented here, proposing that *Libycosaurus* is in fact nested within the *Merycopotamus* radiation, the arrival in Africa of the ancestor of *Libycosaurus* corroborates the hypothesis of a dispersal event from Asia to Africa as proposed by Lihoreau *et al.* (2006, 2014). However, the derivation of *Libycosaurus* would be related to a *M. medioximus-dissimilis* like ancestral stock, rather than a *M. nanus*-like ancestral stock. In this context, the origin of *Libycosaurus* would be viewed as more recent (later) than coeval to the *Merycopotamus* origin, as formerly suggested by earlier phylogenetic results (Lihoreau et al. 2006; Lihoreau et al. 2014). Accordingly, the genus *Merycopotamus* becomes paraphyletic in this phylogenetic context. However, in order for maintaining systematics stability, we propose here that all the species of *Libycosaurus* belong to *Merycopotamus* (following Black 1972), and that *Libycosaurus* represents an African subgenus of *Merycopotamus*. This taxonomic option requires additional paleontological evidence (documenting for instance the number of premolars in *L. algeriensis*) to further test this new systematic proposal.

The new fossil material from Tunisia provides key arguments for rooting the origin of *Libycosaurus* near the origin of *Merycopotamus dissimilis*, most probably from a *M. medioximus*-like ancestral stock in Asia. The latter species, contrary to its precursors, points at widespread distribution characterized by a sudden expansion out of the Indian sub-continent, reaching South-East Asia and Middle East (Lihoreau et al. 2007). This species most probably underwent disruptive evolution in different region of

1
2
3 Asia, with distinct populations in Thailand (a skull has been considered as a new species
4
5 *M. tachangensis* Hanta et al., 2008, which is considered as slightly derived from *M.*
6
7 *medioximus*) and in Iraq (Brunet and Heintz 1983; Lihoreau et al. 2007). We consider
8
9 that a population of *Merycopotamus* (close to the evolutionary degree of *M.*
10
11 *medioximus*) extended its range and shifted westward to reach Africa.
12
13

14
15 The Indian sub-continent is bordered by mountainous arc that limited the
16
17 distribution of anthracotheres outside, at least until the early Tortonian. Following
18
19 Lihoreau et al. (2007) and in accordance with freshwater-constrained distribution of the
20
21 anthracotheres (Lihoreau et al. 2014), the dispersal out of the Indian sub-continent
22
23 might have been facilitated by a major eustatic event (low sea-level) that would have
24
25 connected main river mouths in South Asia. In this province, the Tiger River and
26
27 Euphrates River, as well as the Indus River could have been involved in the connection
28
29 between Middle East and the Indian sub-continent, thus generating a possible dispersal
30
31 pathway for anthracotheres. Recent sedimentological and tectonical studies support the
32
33 existence of these proposed rivers connections. During the Burdigalian (early Miocene),
34
35 fan deposits of the Paleo-Indus River contact those of a river system north of the extant
36
37 Tiger River (Barrier et al. 2018). During this period important dispersal events
38
39 involving many mammalian species occurred between Asia and Africa. These are most
40
41 famously exemplified by the “*Gomphotherium* landbridge” in the Middle East (e.g. Sen
42
43 2013). At this time two anthracotheres genera, *Sivameryx* and *Afromeryx*, dispersed
44
45 from the Indian sub-continent to Africa (Holroyd et al. 2010). We suggest that this
46
47 Burdigalian dispersal was possible due to river mouth connections. In the same way, we
48
49 propose that a new connection between the same river mouths facilitated a dispersal of
50
51 anthracotheres from Indian sub-continent to Africa during Neogene (Tortonian).
52
53
54
55
56
57
58
59
60

The stratigraphical sequence where the earliest *Libycosaurus* (i.e., *L. algeriensis*) is found corresponds to a marine regression phase. The environmental condition of deposits characterizing the whole Beglia Fm., would correspond to this kind of eustatic event (Belghithi et al. 2016). In contrast, the sediments of the Saouaf Fm. correspond to a marine transgressive sequence (Belghithi et al. 2016). We hypothesize that first, the dispersal took place during a regression event or second, at the regression maximum. A main regression event is recorded between 12 Ma and 10.5 Ma in US mid-Atlantic coastal plain (Kominz et al. 2008), and between 12.1 Ma and 10.9 Ma in the northeastern Australian margin (John et al. 2011). This event is framed by the Mi5 and Mi6 isotopic event (Haq et al. 1988; Westerhold et al. 2005; John et al. 2011). The sea level drop is estimated close to 50 m, with a lowstand at 10.4-10.9 Ma (John et al. 2004; Westerhold et al. 2005; Kominz et al. 2008). This event permitted the extension of the hydrographical networks that may have connected temporarily the river mouths of Paleo-Indus River and a paleo-river north to the Tiger River, and likely allowed semi-aquatic mammals to disperse outside the Alpine arc. Following the distributions of fluvio-lacustrine deposits during the Tortonian (Barrier et al. 2018), connections are possible between the Tiger-Euphrate water system and the main trans-Saharan drainage systems as the Nile rivers (Bussert et al. 2018) and the Sahabi rivers (Griffin 2010), providing large dispersal pathway from Middle East to North Africa for fresh-water aquatic mammals.

This dispersal event could therefore serve as a marker to precisely determine the age of the first *Libycosaurus* arrival in Africa at the base of the Tortonian, between 11.3 Ma (the earliest occurrence of a *M. medioximus*-like representatives) and 10.9 Ma or 10.5 Ma (the minimal sea level). This age is crucial for dating the Nementcha Fm. in Algeria and the early phase of deposition of the Beglia Fm. (earlier than Bled Douarah),

both of which record the occurrence of the most primitive species of *Libycosaurus* (*L. algeriensis*). Moreover, the record of *Libycosaurus* in the late Miocene of Oluka in Uganda (Pickford 1991a), indicates that connections between North and East Africa were possible for semi-aquatic mammals, thereby constraining the age of the onset of the Sahara. The specimen, an upper molar, from the Kakara Fm, Uganda, was attributed to *Libycosaurus* cf. *anisae* (Pickford 1991a) and to *L. petrocchii* (Simon et al. 2017), even if the latter must only be restricted to its holotype (see Lihoreau et al. 2014). It is difficult to discriminate *Libycosaurus* species on upper molar morphology but its small size could eventually correspond to a very small specimen of *L. anisae* (Pickford 1991a) or to a specimen of *L. algeriensis*. The age of this specimen is proposed to be early Tortonian (Simon et al. 2017), and it is worth noting that this specimen was found in association with *Tetralophodon*, as is the case at Bir el Ater 3 (Lihoreau, Hautier, et al. 2015). In sum, the Ugandan specimen, as well as the Algerian and the Tunisian materials might represent evidence of the first arrival of *Libycosaurus* in Africa. Besides, the apparent widespread distribution of this taxon would indicate riverine connections between East and North Africa during the early Tortonian. This element brackets the age of the Saharan onset after 10.5 Ma to at least a new period of near-river connection within Sahara, near 7 Ma (Griffin 2002; Lihoreau et al. 2006; Otero et al. 2009).

Conclusions

The evolution of *Libycosaurus* toward a more aquatic life style, a grazer diet and gregarious habit is not a convergent history with *Merycopotamus*, but the same history that took place in Africa. *Libycosaurus algeriensis* is here considered as

1
2
3 morphologically more advanced than *Merycopotamus nanus*, and thus already in course
4 of global ecological shift. Additional paleontological support documenting this species,
5 notably cranial elements, would be necessary for substantiating a new systematic
6 hypothesis according to which *Libycosaurus* would be a subgenus of *Merycopotamus*.
7
8

9
10 Our estimate regarding the dating of the new Tunisian Sidi Hedri locality, where
11 we discovered fossil remains attributable to *Libycosaurus algeriensis*, suggests an age
12 close to the base of Tortonian. *Libycosaurus algeriensis* represents the most ancient
13 record of the genus in Africa so far. *Libycosaurus algeriensis* probably documents a
14 species morphologically close to its Asian ancestor who probably dispersed to Africa
15 only shortly before the first appearance of *Libycosaurus* in the fossil record of Africa.
16 This corresponds to an important African event prior to the *Hippurion* Datum and thus
17 helps resolving African Neogene biochronology more precisely. A thorough review of
18 biostratigraphical correlations of Tunisian Neogene formations using vertebrate fossil
19 data should improve resolution of the local history for establishing an important scale
20 for the Middle-Late Miocene transition in Africa.

Acknowledgment

We would like to thank Baba El-Hadj Mallah, Clarisse Nekoulnang, and Mahamat Adoum (CNRD, N'Djaména, chad), Michèle Morgan and John Barry (Peabody Museum of Harvard University, Cambridge, USA), Wilma Wessels (Utrecht University, Utrecht, Netherland), and Mohammed Mahboubi (Université d'Oran 2, Oran, Algeria) for granting us access to the collection in their care. We also acknowledge Suzanne Jiquel for sample preparation and casting. We thank the anonymous reviewers for their help to improve this manuscript. Fieldwork and post-field researches were supported by the French ANR-ERC PALASIAFRICA (ANR-08-JCJC-0017) and has also benefit from the French ANR program SPLASH (ANR-15-CE32-0010-01) and from grant of the Scientific Council of University of Montpellier.

Declaration of interest statement

Supporting information for Lihoreau *et al.*

I List of characters for cladistics analysis

From Lihoreau *et al.* (2016), Boisserie *et al.* (2017), and 5 new characters (63, 80, 139, 156, 162)

Anterior lower teeth

1. Number of lower incisors:

- 0. three
- 1. two
- 2. one

2. Lower incisor morphology:

- 0. not caniniform
- 1. at least one caniniform lower incisor

3. Relative dimensions of lower incisors:

- 0. all of equal size
- 1. one or two more developed

4. Most developed incisor:

- 0. I/2
- 1. I/3
- 2. I/1

5. Transverse section of lower incisors crowns:

- 0. strongly irregular
- 1. about rounded

6. Lower incisor cervix morphology:

- 0. no deep indentation
- 1. indented cervix, indentation as long as the root diameter on the cervix
- 2. deep indentation longer than the root diameter at cervix

7. Crown of I/1:

- 0. straight
- 1. spatulate, with convex mesial and distal border

8. Presence of a median lingual pillar (lingual rib) on lower I/1:

- 0. yes
- 1. no

9. Lower canine cross section at cervix:

- 0. subcircular
- 1. elliptical

10. Cristids on lower canine enamel caps:

- 0. none
- 1. one distal
- 2. two, one mesial and one distal
- 3. one mesial

11. Wear on lower canine:

- 0. distal wear facet contact with canine
- 1. mesial wear facet contact with I3/

12. Groove on labial side of lower canine:

- 0. no
- 1. yes

13. Groove on lingual side of lower canine:

- 0. no
- 1. yes

14. Lower canine in male:

- 0. fang-like
- 1. premolariform
- 2. incisiform

15. Crown of lower canine in male:

- 0. small near premolar size
- 1. at least twice the premolar size
- 2. prolonged growth to ever-growing

Lower premolars

16. P/1 roots:

- 0. one
- 1. two

17. Paraconid on lower premolars:

- 0. no
- 1. yes

18. Accessory cusp on the preprotocristid of all lower premolars:

- 0. none
- 1. at least one
- 2. at least two

4
5 **19. Elongated P/3:**
6 0. no (shorter or equal than M1 lenght)
7 1. yes (longer than M1 lenght)
- 8 **20. Three lobed P/3:**
9 0. no
10 1. yes
- 11 **21. Orientation of postprotocristid on P/3:**
12 0. distal
13 1. distolingual
14 2. distolabial
- 15 **22. High cingulid on labial face of P/3:**
16 0. no
17 1. yes
- 18 **23. Endoprotocristid on P/3:**
19 0. no
20 1. yes
- 21 **24. Entoconid on P/3:**
22 0. never
23 1. at least on some specimens
- 24 **25. P/3 hypoconid:**
25 0. no
26 1. yes
- 27 **26. Preprotocristid mesiolingualy curved on P/3:**
28 0. no
29 1. yes
- 30 **27. Mesial accessory cusp on preprotocristid on P/3:**
31 0. simple slope
32 1. Shoulder like structure on lateral view
33 2. adorned with accessory cusp
- 34 **28. Lingual contour at cervix of P/4 in occlusal view:**
35 0. convex to straight
36 1. concave
- 37 **29. Labial wall on P/3 or P/4:**
38 0. convex
39 1. concave
- 40 **30. Change in the orientation of the preprotocristid mesialy to the junction of accessory mesiolingual crest on lower premolars:**
41 0. no
42 1. yes
- 43 **31. Orientation of the endoprotocristid on P/4:**
44 0. absent
45 1. separated from postprotocristid at the protoconid apex and then straight and distolingual
46 2. fused with postprotocristid in part and then curved mesiolingually
- 47 **32. Distolingual cingulid on P/4 in lingual view:**
48 0. forming a continuous wall lingually until the distostyloid
49 1. reaching the level of the distal basin and keeping be shallow until the distostyloid
50 2. reaching the level of distal basin and then being high when joigning the distostyloid (distolingual notch of cingulid)
- 51 **33. Presence of a preentocristid on P/3 and/or on P/4:**
52 0. no
53 1. yes
- 54 **34. Mesiolingual secondary cristid on P/4 (cristid connecting lingual margin and preprotocristid):**
55 0. no
56 1. yes
- 57 **35. Labial cingulid form a V (indented) on P/4 before to reach the distal cingulid:**
58 0. no
59 1. yes
- 60 **36. Marked postprotofossid on P/4:**
61 0. absent
62 1. present
- 63 **37. Postectoprotocristid on P/4:**
64 0. no
65 1. yes
- 66 **38. Hypoconid on P/4:**
67 0. no
68 1. yes (even incipient)
- 69 **39. Ectoprotofossid on P/4:**
70 0. absent
71 1. frequent
- 72 **40. Postprotocristid position on P/4 (in regard of a mesiodistal midline):**
73 0. median or labial
74 1. lingual

Lihoreau et al. Supporting information

- 1
2
3
4
5 **41. Endoprotostid on P/4:**
6 0. reaches lingual border
7 1. reaches lingual cingulid wall
8
9 **42. Postentocristid on P/4:**
10 0. no
11 1. short
12 2. long, which reaches cingulid distally
13
14 **43. Preprotocristid direction on P/4:**
15 0. mesiolingual (but can be moderately curved)
16 1. lingual then mesial
17 2. mesial then lingual
18
19 **44. Entostyloid on P/4:**
20 0. no
21 1. yes
22 2. continuous junction with cingulid without
23 clear apex
24
25 **45. Metaconid on P/4:**
26 0. no
27 1. yes (indeed an entostyloid surrounded by
28 cingulid and not formed by cingulid)
- 29
30
31 **46. Premetacristid on lower molars:**
32 0. strong
33 1. reduced or missing
34
35 **47. Paraconid on lower molars, almost on
36 unworn specimens:**
37 0. yes
38 1. no
39
40 **48. Lower molar trigonid:**
41 0. equal in height with talonid
42 1. higher than talonid
43
44 **49. Connection between premetacristid and
45 preprotocristid on lower molars:**
46 0. yes
47 1. no
48
49 **50. Postectoprotocristid on lower molars:**
50 0. absent
51 1. reduced in the valley to fully developed at
52 least on M/1
53
54 **51. Postprotofossid on lower molars at least
55 on M/3:**
56 0. no
57 1. yes
58
59
60
- 52 **52. Postmetacristid on M/1-2:**
53 0. curving toward postprotocristid forming a
54 transverse bridge with it
55 1. orientated straight toward the centre of the
56 tooth
57 2. forming a rounded postmetaconulid not
58 preferentially orientated
59 3. joins prehypocristid
60
61 **53. Ectoprofossid on lower molars:**
62 0. absent
63 1. present
64
65 **54. Ectometafossid on lower molars:**
66 0. yes
67 1. no
68
69 **55. Endometacristid on lower molars:**
70 0. no or slightly expressed much more like an
71 enamel fold
72 1. present
73
74 **56. Postectometacristid on lower molars:**
75 0. lightly marked to absent
76 1. always present and well-marked
77
78 **57. Premetafossid on lower molars:**
79 0. present
80 1. absent
81
82 **58. Preentocristid:**
83 0. absent
84 1. present
85
86 **59. Preentocristid connects:**
87 0. endohypocristid
88 1. prehypocristid toward the cuspid apex
89 2. prehypocristid toward its mesial extremity
90
91 **60. Postectoentocristid on lower molars:**
92 0. absent
93 1. present but more like a keel on cusp
94 2. present and well individualized from the
95 cusp
96
97 **61. Ectoentocristid:**
98 0. present
99 1. absent
100
101 **62. Postentocristid on lower molars:**
102 0. absent
103 1. present
104
105 **63. Postentocristid mesiodistally oriented and**

Lihoreau et al. Supporting information

comprised between the posthypocristid and the entoconid (=the entoconid fold):

- 0. no
- 1. yes

64. Prehypocristid dividing in two mesial arms on lower molars:

- 0. yes
- 1. no

65. Prehypocristid inflated (not salient when unworn)) in transverse valley of lower molars:

- 0. no
- 1. yes (even to form a conulid)

66. Prehypocristid reaches:

- 0. median part of transverse valley
- 1. lingual part of transverse valley
- 2. labial part of the transverse valley

67. Main arm of prehypocristid connects:

- 0. trigonid distal walls (junction between cristids from metaconid and protoconid)
- 1. postmetafossilid
- 2. lingual margin of transverse valley
- 3. postmetacristid

68. Posthypocristid joins:

- 0. nothing or distostyliid
- 1. posttentocristid
- 2. postectoentocristid

69. Endohypocristid on lower molars:

- 0. absent
- 1. present

70. Posthypofossilid on lower molars:

- 0. absent
- 1. present

71. Entostyliid on lower molars that could sometimes be linked to an entocristyliid:

- 0. never
- 1. frequently present

72. Ectostyliid on lower molars:

- 0. no cingulid
- 1. a shallow and constant cingulid in front of the transverse valley
- 2. frequently developed cingulid in a /some stylid at least on m1

73. Ectocrystilid on lower molars :

- 0. no
- 1. yes even if variable

74. Cingulid surrounding m/3 hypoconulid:

- 0. no specimen exhibiting such extension
- 1. occasionally bordering the labial wall

75. Presence of one or many posttentostyliid on M/3:

- 0. no
- 1. yes

76. Ectohypocristulid on M/3:

- 0. absent
- 1. not complete
- 2. present joining the summit of hypoconulid

77. Distostyliid on M/1-M/2:

- 0. median
- 1. lingual
- 2. none

78. Mesial part of loop-like hypoconulid:

- 0. open
- 1. pinched

79. Posthypocristulid:

- 0. complete
- 1. incomplete

80. Posthypocristulid incomplete due to:

- 0. a groove separates the cristid in two part
- 1. It lacks a part or totality of the cristid

81. Entoconulid:

- 0. no
- 1. yes

Anterior upper teeth

82. Number of upper incisors:

- 0. 3
- 1. 2
- 2. none

83. Central upper incisor:

- 0. morphologically similar to I2/ and/or I3/
- 1. peg-like, morphologically different from others
- 2. caniniform

84. I3/ reduced in size compared to I1/:

- 0. no
- 1. yes

85. Upper canine morphology:

- 0. strong, with circular or elliptic cross section

		Lihoreau et al. Supporting information
1	1.	strong and laterally compressed (blade-like)
2	2.	premolariform

	1.	present
	103.	P4/ protocone:
	0.	rounded
	1.	crescentic
	104.	In lingual view protocone of P4/ is:
	0.	displaced mesially
	1.	median
	105.	P4/ mesial margin:
	0.	concave
	1.	convexe
	106.	Strong development of distostyle on P4/:
	0.	no
	1.	yes
	107.	Mesial accessory cusp on P4/ that can be linked to mesiostyle:
	0.	no
	1.	yes
	108.	P4/ metacone:
	0.	absence
	1.	presence
	109.	P4/ paracone higher than the protocone:

- 1
2
3
4
5 0. slightly higher than protocone
6 1. much higher than protocone

7 **110. P4/ endoparacrista:**

- 8 0. absence
9 1. presence

10 **111. Distal accessory cusp on postprotocrista of P4/ that can be linked to distostyle:**

- 11 0. no
12 1. yes

13 **Upper molars**

14 **112. Height of lingual cingulum compared to unworn protocone height on upper molars:**

- 15 0. one third
16 1. half
17 2. no cingulum

18 **113. Mesio-distal ribs development of labial 24 cusps of upper molars:**

- 19 0. almost half the molar length
20 1. pinched (inferior to one third of molar
21 length)
22 2. enlarged (superior to half the molar length)

23 **114. Postectoprotocrista:**

- 24 0. absent
25 1. present

26 **115. Postprotocrista:**

- 27 0. present
28 1. absent

29 **116. Protocone and metaconule junction on 34 upper molars:**

- 30 0. none
31 1. premetacristule with postectoprotocrista
32 2. premetacristule with postprotocrista
33 3. postprotocrista and lingual part of
34 metaconule

35 **117. Premetacristule divided in two mesial 40 arms:**

- 41 0. no
42 1. yes

43 **118. Ectometacristule on upper molars:**

- 44 0. absent
45 1. present at least on M1/
46 2. not frequent and only on M2/ or M3/

47 **119. Postmetafossule:**

- 48 0. absent

49 Lihoreau et al. Supporting information

- 50 1. present

51 **120. Secondary cristule labial to metaconule 56 eventually an endometacristule or enamel knob:**

- 57 0. no
58 1. yes

59 **121. Distostyle on upper molars:**

- 60 0. yes
1. no

122. Distostyle position on upper molars levels:

0. metaconule
1. metacone

123. Secondary ectometafossule lingual to 30 ectometacristule:

0. absent or very light
1. present mesially at least on M1/ linked to
ectometacristule

124. Paraconule on upper molars:

0. present
1. absent

125. M2/ paraconule when present:

- similar in size with protocone
smaller than protocone

126. Postparacristule extends to connect:

0. none
1. base of the paracone
2. transverse valley

127. Preparacrista connects the parastyle:

0. no, separated by a groove
1. yes, lingually
2. yes, labially

128. Endoparacrista on upper molars:

0. absence
1. presence

129. Ectoparafoossa on upper molars:

0. no
1. yes

130. Ectocristyle:

0. frequently present
1. absent

131. Premetacrista and postparacrista 54 connect:

0. no connection
1. direct connection in a centrocrista

		Lihoreau et al. Supporting information
1	2.	connection to mesostyle (via ectocristyle or not)
2	1.	fully fused lingual roots
3	2.	three roots
4	132. Endometacrista and endometacristule forming a transverse crest:	143. Lingual cingulum on upper molars:
5	0. absence	0. no
6	1. presence	1. yes
7	2.	2. developed in entostyle
8	133. Parastyle development:	144. Hypocone on upper molars (at least M2/):
9	0. enamel knob	0. yes
10	1. smaller or equal than mesostyle	1. no
11	2. larger than mesostyle	
12	134. Premetacristule invade labial part of the transverse valley:	145. Shape of M1/:
13	0. no	0. triangular
14	1. yes	1. quadrate
15		
16	135. Position of metaconule on upper molar:	146. Shape of M3/:
17	0. labial side of the protocone	0. triangular
18	1. distal side of the protocone	1. quadrate
19		
20	136. M2/ metaconule:	147. M3/ size:
21	0. similar in size with protocone	0. Larger than M2/
22	1. smaller than protocone	1. equal in size with M2/
23	2.	2. reduced (less than 60%)
24		
25	137. Mesostyle on upper molars:	148. Mesiolingual style on upper molar mesial cingulum:
26	0. no	0. no
27	1. yes	1. yes
28		
29	138. Mesostyle:	Mandible
30	0. enamel knob	149. Symphysis morphology in sagittal section, ventral border:
31	1. half to the size of labial cusp	0. convex
32	2. larger than labial cusp	1. straight to almost straight
33		2. concave
34	139. Cingulum at the junction between postparacrista and premetacrista forming labial structure on mesostyle:	150. Symphysis morphology in sagittal section, dorsal border:
35	0. high triangular cingulum	0. convex
36	1. wing-like cingulum	1. straight or almost straight
37	2. low or absent cingulum	2. markedly concave
38		
39	140. Division of the mesostyle on upper molar:	151. Diastem C-P/1:
40	0. no, one style or continuous cristae	0. absent
41	1. two apices in unworn molars but still connected by cristae	1. present
42	2. fully isolated style apices	
43		
44	141. Metastyle:	152. Bone fusion at symphysis in adult specimens:
45	0. reduced to enamel knob or absent	0. no
46	1. fully developed	1. yes
47		
48	142. Root fusion on upper molars:	153. Maximal thickness of the symphysis in sagittal section:
49	0. four roots with occasional fusion close to cervix, the root apices always remaining free

0. in the middle part
1. in the rostral part
2. in the nucal part
- 154. Symphysis extension:**
0. extends nuchally between C and P/1
1. extend nuchally between P/1 and P/3
2. extends nuchally to P/3
- 155. Number and position of main external foramen:**
0. numerous
1. only one below the anterior part of the premolar row
2. two, one below the anterior part and the other below the posterior
- 156. Mandibular notch:**
0. no
1. yes, long extension behind coronoid process
2. yes, short extension below m/3
- 157. Transverse constriction of mandible at C-P/1 diastema:**
0. no
1. yes
- 158. Mandibular protuberance at the C/P/1 level:**
0. no
1. yes
- 159. P/1-P/2 diastema:**
0. absent
1. present
- 160. P/2-P/3 diastema:**
0. yes
1. no
- Cranium**
- 161. Opening of internal choanæ:**
0. at M3/
1. nucal to M3/
- 162. Opening of main palatal foramen:**
0. at palatine-maxillary junction in front of molars to P3
1. on maxillary in front of P2-P1
2. on maxillary cranial to P1
- Enamel microstructure**
- 163. Enamel ornamentation:**
- 164. Schmelzmuster composed of:**
0. two layers
1. three layers
2. one layer
- 165. Inner radial enamel:**
0. absent
1. present
- 166. HSB percent of Schmelzmuster:**
0. absent
1. less than 75%
2. more than 76%
- 167. Outer radial enamel:**
0. less or equal to 20%
1. more than 20%
- 168. Hsb zone:**
0. thin with bands always less than 100µm
1. large (equal or more than 100µm)
- 169. Regular aspect (constant width):**
0. yes
1. no
- 170. HSB variable (SD>20):**
0. no
1. yes
- 171. HSB angle with EDJ:**
0. >70°
1. <70 °
- 172. Orientation of HSB:**
0. straight
1. bent
- 173. HSB definition (decussation angle and size of transition zone):**
0. clear
1. blurry
- 174. Division of HSB:**
0. anastomosis
1. bifurcation
2. no division
- 175. HSB configuration:**
0. curved
1. transverse

7 **Other early cetartiodactyl families**

8 **Cebochoeridae** Lydekker, 1883

- 9 *Cebochoerus campichii* Pictet 1855-57
10 • Temporal and geographical distribution
11 Middle Eocene; Western Europe
12 • Origin of examined material
13 - Robiac, France (UM)
14 • References: (61, 70)

15
16 **Choeropotamidae** Owen, 1845

- 17 *Choeropotamus depereti* Stehlin 1908
18 • Temporal and geographical distribution
19 Middle Eocene; Europe
20 • Origin of examined material
21 - Euzet, France (UM)
22 • References: (61, 70-71)

- 23
24 *Hallebune krumbiegeli* Erfurt and Sudre, 1995
25 • Temporal and geographical distribution
26 Middle Eocene; Europe
27 • Origin of examined material
28 - Geiseltal, Germany (cast UM)
29 • References: (61, 70-71)

30
31 *Amphirhagatherium* spp corresponds to the two following species :
32 *Amphirhagatherium neumarkensis* Erfurt and Haubold 1989

- 33 • Temporal and geographical distribution
34 Middle-Late Eocene; Europe
35 • Origin of examined material
36 - Geiseltal, Germany (Cast UM)
37 • References: (61, 70-71)

- 38 *Amphirhagatherium weigelti* (Heller, 1934)
39 • Temporal and geographical distribution
40 Middle-Late Eocene; Europe
41 • Origin of examined material
42 - Geiseltal, Germany (Cast UM)
43 • References: (61, 70-71)

44 **Mixtotheriidae** Pearson, 1927

45 *Mixtotherium* spp. corresponds to the following species:

46 *Mixtotherium gresslyi* Rutimeyer, 1891

- 47 • Temporal and geographical distribution
48 Middle-Late Eocene; Europe
49 • Origin of examined material
50 - Egerkingen, Switzerland and La Defense, France (casts UM)
51 • References: (70)

52 *Mixtotherium lavergnensis* (Sudre, 1977)

- 53 • Temporal and geographical distribution
54 Middle-Late Eocene; Europe
55 • Origin of examined material
56 - Lavergne, France and Eclepens-gare, Switzerland
57 • References: (72)

5 Amphimerycidae Pearson, 1927*6 Amphimeryx murinus* (Cuvier, 1822)

- 7 • Temporal and geographical distribution
 - 8 Late Eocene; Europe
- 9 • Origin of examined material
 - 10 - Escamps, Rosières 2 and St Néboule, France (casts UM)
- 11 • References: (61, 70, 72)

13 Anoplotheriidae Bonaparte, 1850*14 Diplobune minor* (Filhol, 1877)

- 15 • Temporal and geographical distribution
 - 16 Late Eocene-early Oligocene; Europe
- 17 • Origin of examined material
 - 18 - Itardies, France (UM)
- 19 • References: (73)

20 Dacrytherium ovinum Owen, 1857

- 21 • Temporal and geographical distribution
 - 22 Late Eocene; Europe
- 23 • Origin of examined material
 - 24 - Fons and Euzet, France (UM)
- 25 • References: (70, 72)

27 Xiphodontidae Flower, 1884*28 Xiphodon castrensis* Kowalewsky, 1873

- 29 • Temporal and geographical distribution
 - 30 Late Eocene; Europe
- 31 • Origin of examined material
 - 32 - Robiac and Le Bretou, France (UM)
- 33 • References: (70, 72)

35 Cainotheriidae Camp and Van der Hoof, 1940*36 Paroxacron valdense* (Stehlin, 1906)

- 37 • Temporal and geographical distribution
 - 38 Late Eocene-Early Oligocene; Europe
- 39 • Origin of examined material
 - 40 - Escamps, France (UM)
- 41 • References: (70, 72)

43 Entelodontidae Lydekker, 1883*44 Entelodon* spp corresponds to the two following species :*45 Entelodon deguilhemi* Repelin, 1919

- 46 • Temporal and geographical distribution
 - 47 Early Oligocene; Europe
- 48 • Origin of examined material
 - 49 - Villebramar and Quercy, France (cast UM2)
- 50 • References: (74)

51 Entelodon magnum (Aymard, 1846)

- 52 • Temporal and geographical distribution
 - 53 Early Oligocene; Europe
- 54 • Origin of examined material
 - 55 - Ronzon and Quercy, France
- 56 • References: (74)

Lihoreau et al. Supporting information

Merycoidodontidae Lydekker, 1883

Merycoidodon sp

- Temporal and geographical distribution
 - Oligocene; North America
- Origin of examined material
 - Big Badland, South Dakota, USA (UM2)
- References: (75)
