²Department of Botany, Swedish Museum of Natural History, PO Box 50007, 104 05 Stockholm (Sweden).

Pycnandra longiflora (Sapotaceae) belongs to the largest endemic genus in New Caledonia. It is only known from the type collection made in 1861–67 at the obscure locality “Gatope”. Relocation of this species has been of high priority for more than a decade, but without success. *Pycnandra longiflora* was therefore recently declared extinct. However, a population was recently discovered near a mining site at Onajiele, in the Ouazangou-Taom massif, and it is revealed that *P. longiflora* has the most spectacular flowers in the entire genus, being large and bicoloured in red and yellow. A thorough description is here outlined and we propose a preliminary IUCN status as Critically Endangered.

Key words: Extinct species, rediscovering, extended description, prospection

Sapotaceae was the first plant family to be treated for Flore de Nouvelle-Calédonie et Dépendances with 80 recognized species at that time (Aubréville 1967). Identification of genera and species has been highly problematic due to doubtful generic limitations and insufficient material for proper species description. In the 1990s several putative new species were tentatively proposed, which were believed to be threatened with extinction, including “*Leptostylis* sp.1 V.6850” and “*Planchonella* sp.1 V.6585” (Jaffré *et al.* 1998). Other species were considered doubtful since they were only known from the type collections made in the 1860s, including *Planchonella vieillardii* (Baill.) Dubard (1912: 58) from Gatope, *Leptostylis micrantha* Beauvisage (1901: 88) from Art Island, and *L. longiflora* Benth in Benth & Hooker (1876: 659), also from Gatope (Bouchet *et al.* 1995). Revision of the family for New Caledonia was clearly needed, a work we embarked on more than a decade ago, resulting in a new generic classification (Bartish *et al.* 2005; Swenson *et al.* 2007a, 2008, 2013, 2015) as well as 42 new species endemic for New Caledonia (Swenson *et al.* 2007b, 2009, 2010a, 2010b, 2010c, 2012, 2016; Munzinger & Swenson 2009, 2015; Munzinger 2015).

Leptostylis Benth was revised by Vink (1957), who described three new species, accepted seven in total, and selected *L. longiflora* as the type of the genus, despite it being only known from the type collection. The type was collected in 1861–67 at Gatope by Émile Deplanche (1824–1874), a French naval surgeon and botanist (Morat 2010). *Leptostylis* is readily identified by its opposite leaves and four sepals, but the group is nested within *Pycnandra* and was relegated to subgeneric level to maintain monophyly (Swenson & Munzinger 2009; Swenson *et al.* 2015). Nevertheless, subgenus *Leptostylis* was in urgent need of revision in order to sort out several taxonomic problems and to enable transfer of the recognised species to *Pycnandra*. We therefore undertook extensive fieldwork in New Caledonia and in particular Dominique Fleurot intensively searched the maquis vegetation in the Gatope Peninsula near Koné in the hope of relocating *P. longiflora*. All in all, 413 individuals of *Pycnandra* were found, but all belonged to another species, *P. filipes* subsp. *filipes* (Benth) Munzinger & Swenson (2015: 97). Unable to relocate *P. longiflora*, we eventually considered the species to be extinct (Munzinger & Swenson 2015; Swenson & Munzinger 2016), a conclusion that we here fortunately can reject.

Our publications alerted an amateur botanist, Rosa Scopetra, in November 2015 that a species she had followed for years could possibly be the presumed extinct species *Pycnandra longiflora*. Recently, she sent pictures and specimens with flowers and fruits to one of us (JM in Montpellier), material easily confirmed as the plant unseen for 150 years –*Pycnandra longiflora*. We were at once astonished by the spectacular bicoloured flowers with red tubes and yellow corolla lobes that matched the type collection from which the colour cannot be deduced (Fig. 1). Without doubt, *P. longiflora* has the largest and the most beautiful flowers in the entire genus. With this unexpected rediscovery it is possible to complete the description of a very rare species and change the proposed IUCN status from Extinct to Critically Endangered.

Material and methods

We used herbarium specimens [*Munzinger leg. Scopetra 7519, 7522*], flowers and fruits preserved in alcohol, images, and field observations (including individuals counted) by Rosa Scopetra. We apply IUCN criteria (IUCN 2012) for evaluating threat status, using ‘Geocat’ software online (Bachman *et al.* 2011) to calculate extent of occurrence (EOO) and area of occupancy (AOO). A topographic image of the population’s distribution was made with the software ArcGIS © by using georeferenced individuals” (excluding the type locality).

Pycnandra longiflora (Benth.) Munzinger & Swenson, Austral. Syst. Bot. 28: 101 (2015) (Fig. 1)

FIGURE 1. *Pycnandra longiflora*, A. Habit of open maquis, B. Flowering branch, C. Fruits with long persistent styles, D. Seeds from one- or two-seeded (arrow) fruits. Pictures A–C from Rosa Scopetra, D from Jérôme Munzinger.

Expanded description

Slender shrub usually 1.7 m tall (to rarely 4 m tall), with grey–brownish branches. Leaves opposite, subsessile, obovate, narrowly obovate or suborbicular, small, glabrous, coriaceous, 1.3–4.0(–7.5) x 0.9–3.5(–4.0) cm; base round to cordate; secondary venation usually of 5 pairs; tertiary veins indistinguishable. Flowers axillary and solitary; pedicels filiform, ~12 mm long, glabrous. Sepals ~3 mm long, ovate, glabrous. Corolla tubular, red, 30–32 mm long; corolla lobes 6–8, pale yellow, oblong, 6–7 mm long. Stamens inserted slightly below the tube orifice, exserted; filaments filiform, ~12 mm long; anthers 2.5–3.5 mm long. Gynoecium conical, pubescent around the base; ovary 1.5 x 1.0 mm; style filiform, up to 50 mm long in flowering specimens, well exserted and available for pollinators, glabrous, of the same colour as the corolla lobes and filaments. Fruit pyriform, widest at the base, 20–25 x 8–10 mm (slightly flattened and 15 mm wide if containing two seeds), black when mature, glabrous, with a 35–50 mm long persistent style; seeds usually 1, 17–21 x 8–10 mm, ovoid; testa pale brown, thin (0.5 mm), usually with reddish dots; seed scar oval to narrowly ovate, 15–20 % of seed circumference and 100% of the seed length, with nearly parallel margins; cotyledons plano-convex, cream, smooth, endosperm absent.

Ecology

Pycnandra longiflora occurs on hypermagnesium brown soils in quite open maquis, between 55 and 140 m elevation (Fig. 1A). The shape of the flowers, with long tube and well-exposed stamens and style, indicates that it is probably bird pollinated (Faegri & Van Der Pijl 1979).

Conservation status

The newly revealed locality of *Pycnandra longiflora* is near Onajiele in the Ouazangou-Taom massif. The species occurs at two adjacent sites and has a calculated EOO of 0.6 km² and AOO of 8 km². One hundred and seventy six individuals have been counted in this very limited area that easily could be ruined by a single fire, forest clearance, or an enlargement of the truck access to the mining concession (Fig. 2). Thus, following the IUCN terminology and recommendations, *P. longiflora* occurs on a single location and is therefore best assigned a preliminary IUCN status as Critically Endangered [CR B1ab(iii)+2ab(iii)].

What does this discovery teach us about Vieillard's collections?

An important early explorer in New Caledonia was Eugène Vieillard (1819–1896) and many types are based on his collections (more than 150 species have the epithet “*vieillardii*”). However, his numbering system was awkward and Morat (2010) finds it “special and irrational”, and he indeed used a system in which he numbered the species as he perceived them instead of giving each collection a unique number. This has caused much confusion for his successors, a problem scientists still struggle with. The worst case known was found in *Sorthocalyx* (Sapindaceae), where three different species of the same genus were mixed in a “single type collection” (Pierre *et al.* 2014). In addition, Vieillard used only a few locality names, such as Canala, Gatope, Balade and Wagap, which were military posts and probably represent very vague areas and not the real villages having these names (MacKee & MacKee 1981). Therefore, we assume that Deplanche used “Gatope” in the same meaning as Vieillard and most likely referred to the North-Western quarter of the main island, Grande Terre. Thus, if a taxon is sought

in a location such as Canala, Balade, Gatope or Wagap, following information provided by Vieillard, we suspect that a much larger area of the coast and mountains should be surveyed.

Conclusion

Pycnandra longiflora is not extinct and grows less than 600 metres from the main road (RT1) of “Grande-Terre”, close to an accessible track (Figure 2). This is a very important locality of native vegetation as a new species of Myrtaceae, *Eugenia plurinervia* Snow, Munzinger & Callm. (2016: 212), also occurs here. Several other rare species such as *Planchonella minutiflora* Munzinger & Swenson (2009: 182), *Croton cordatulus* Airy Shaw (1978: 387), *Euodia tietaensis* (Guillaumin) T.G. Hartley (2001: 56) are also present, which clearly indicates that the place has high conservation value. The rediscovery of this *P. longiflora* supports continuing botanical surveys in New Caledonia, to provide sound data for conservation assessments.

Acknowledgements

Great thanks to Rosa Scopetra for her valuable observations and sharing passion for plants, Dominique Fleurot and Jean-Pierre Butin for many field observations of *Pycnandra* subgen. *Leptostylis*, DIMENC for providing “cadastre minier”, Peter Weston and anonymous reviewers for comments.
