Zwitterionic Functionalizable Scaffolds with Gyroid Pore Architecture for Tissue Engineering

Nina Yu Kostina, Sebastien Blanquer, Ognen Pop-Georgievski, Khosrow Rahimi, Barbara Dittrich, Anita Höcherl, Jiří Michálek, Dirk W. Grijpma, and Cesar Rodriguez-Emmenegger*

Stereolithography-assisted fabrication of hydrogels of carboxybetaine meth-14 15 acrylamide and a α, ω -methacrylate poly(D,L-lactide-*block*-ethylene glycol-16 *block-*D,L-lactide) telechelic triblock macromer is presented. This technique 17 allows printing complex structures with gyroid interconnected porosity pos-18 sessing extremely high specific area. 19 Hydrogels are characterized by infrared spectroscopy, X-ray photoelectron 20 21 spectroscopy, and confocal laser scanning microscopy. The copolymerization 22 with zwitterionic comonomer leads hydrogels with high equilibrium water 23 content, up to 700% while maintaining mechanical robustness. The intro-24 duction of carboxybetaine yields excellent resistance to nonspecific protein 25 adsorption while providing a facile way for specific biofunctionalization with a 26 27 model protein, fluorescein isothiocyanate labeled bovine serum albumin. The

²⁸ homogeneous protein immobilization across the hydrogel pores prove the

accessibility to the innermost pore volumes.

The remarkably low protein adsorption combined with the interconnected $\frac{30}{31}$

 $\frac{1}{32}$ nature of the porosity allowing fast diffusion of nutrient and waste product

and the mimicry of bone trabecular, makes the hydrogels presented here

highly attractive for tissue engineering.

³⁷₃₈ **1. Introduction**

The primary goal of tissue engineering is to provide a biological
surrogate to regenerate damaged or malfunctioning tissues.^[1-4]
The reconstruction of most of the tissues requires a template
guiding the organization of cells. Thus, scaffolding was introduced to tissue engineering to provide active support and

signals for cells' growth, migration, and 13 new tissue formation.^[1,5,6] Cell migration 14 is controlled by a complex set of mecha-15 nisms that are affected not only by extra-16 and intracellular signaling but also by 17 surrounding extracellular environment.^[7] 18 Scaffold microstructure, such as porosity, 19 pore size and shape, specific surface area, 20 interconnectivity, has been shown to sig-21 nificantly affect cell adhesion, growth, and 22 differentiation. Such scaffolds are used 23 for in vivo regeneration of various tissues, 24 such as skin, cartilage, bone, and periph- 25 eral nerves.^[7-11] Access to nutrients is a 26 cornerstone for cell growth and survival. 27 Thus, interconnectivity of pores are essen- 28 tial for unrestricted fluid flow through 29 the pore space and to ensure diffusion 30 of nutrients, metabolic waste products, 31 cytokines, and paracrine factors through 32 the scaffold.^[12] 33

Conventional strategies for scaffold 34 preparation rely on the covalent or phys- 35 ical cross-linking of polymers to create 36 a matrix.^[13,14] However, the size of such 37

mesh (nanometer scale) is well below cell size (larger than 38 several μ m) which makes it impossible for cells to crawl and 39 colonize the whole matrix. To circumvent this, several strate-40 gies to create macroporosity (micrometer scale) have been 41 introduced, including solvent casting/particulate leaching, 42 fibril networking, and phase separation.^[15–20] However, the use 43

11

12

of these techniques is limited due to the difficulty of having a 1 2 perfect control over the internal pore architecture resulting in 3 structures with irregular pore sizes and often poor pore inter-4 connectivity.^[21] Alternatively, the advances in additive manu-5 facturing significantly improved the production of scaffolds with precise geometry and internal morphology.^[22-24] Among 6 7 them, stereolithography is one of the most developed computer-aided rapid prototyping technique.^[12,23,24] It exploits the 8 3D-controlled solidification of liquid-based resins by photopo-9 10 lymerization. The structure is polymerized in a layer-by-layer 11 manner which allows the fabrication of complex 3D scaffolds with precise external and internal architecture with the highest 12 accuracy.^[12,24-26] In particular gyroid-type structures can be 13 written with very high precision. Gyroid structures of various 14 length scales are ubiquitous in nature from membranes of orga-15 nelles to milk particles.^[27] The triply periodic gyroid-structure 16 17 has unique properties such as the highest surface area available 18 and perfectly interconnected porosity.^[28]

19 For tissue engineering not only is the architecture of the 20 pores important but also the chemistry of the exposed surface. 21 The polymers used for stereolithography play an important role in the scaffold fabrication. Photo-cross-linkable polymer 22 23 solutions-resins-are often based on the mixture of (meth) 24 acrylate-functionalized oligomers, photoinitiators, and a nonvolatile solvent and the viscosity of the mixture is carefully 25 26 optimized.^[23,29] However, the surfaces generated from such 27 polymers are rapidly fouled by proteins from the tissue culture 28 media causing an abundance of negative side effects.

29 To induce specific cell attachment, the surface of the scaffold should be decorated with biological cues, such as pep-30 31 tides, or proteins interacting with integrin receptors of the 32 cell.^[30,31] However, it becomes very challenging for real application when the decorated scaffold comes in contact with 33 34 biological fluids, such as blood plasma or other bodily fluids. 35 This induces nonspecific protein adsorption, that is, protein 36 fouling, leading to irreversible changes in the properties of the material.^[32,33] This protein fouling interferes with the sign-37 aling mechanisms by masking the biological elements immo-38 39 bilized at the surface and by creating a film of proteins which supports the nonspecific adhesion of cells.^[32-42] Thus the fab-40 rication of materials able to resist nonspecific protein adsorp-41 tion is essential.^[42] Although several strategies to modify the 42 surface of 2D materials with coatings resistant to fouling have 43 been achieved, the problem of protein fouling for 3D scaffolds 44 used in tissue engineering is generally neglected.[33,35,37,43] 45 Only a few attempts were made in the preparation of 3D scaf-46 folds able to resist protein fouling and most of them were 47 48 based on poly(ethylene glycol) (PEG).^[34,38,39,44,45] However, 49 recently Riedel et al. proved that their contact with real bio-50 logical media led to fouling regardless of the type of polymer architecture.[33,37,46,47] None of the PEG-based surface modi-51 52 fications could resist the fouling from human blood plasma. The deposits on the best antifouling brushes consisted of 53 54 apolipoprotein A-I, apolipoprotein B-100, complement C3, 55 complement C4-A, complement C4-B, Fbg, histidine-rich glycoprotein, the Ig mu chain C region, and HSA. These proteins 56 57 were ubiquitous in all of the deposits on PEG-based surfaces suggesting some degree of biospecificity, thus alternative to 58 PEG should be sought.^[46] 59

Macromolecular Bioscience www.mbs-journal.de

Previously, it has been shown that polymers based on zwitte- 1 rionic carboxybetaines are able to completely suppress fouling 2 from complex biological media, such as saliva, urine, cerebro-3 spinal liquid, blood plasma, and whole blood.^[35,37,48,49] Recently, 4 our group has introduced antifouling hydrogels consisted of 5 zwitterionic carboxybetaines.^[38,39] These hydrogels were pre-6 pared by copolymerization of 2-hydroxyethyl methacrylate with 7 carboxybetaine acrylamide or methacrylamide and showed a 8 dramatic decrease of protein fouling from complex biological 9 fluids, such as fetal bovine serum and undiluted human blood 10 plasma.^[38,39] Additionally, the carboxybetaine moieties endowed 11 hydrogels with available functional groups which can be utilized 12 for the immobilization of specific biological molecules.^[38,39,50] 13

Herein we introduce a novel type of zwitterionic anti-14 fouling hydrogels with precise gyroid pore architecture by 15 employing the unique properties of nonfouling zwitterionic 16 poly(carboxybetaine)s and a technique for fabrication of scaf-17 folds with designed architecture, such as stereolithography. The 18 hydrogels were prepared by copolymerization of zwitterionic 19 carboxybetaine methacrylamide (CBMAA) and a macromer 20 α, ω -methacrylate poly(D,L-lactide-block-ethylene glycol-block-D,L-21 lactide) telechelic triblock copolymer (MA-PDLLA-PEG-PDLLA-22 MA) as cross-linker. The poly(D,L-lactide) (PDLLA) block is 23 introduced for biodegradability, while the poly(ethylene glycol) 24 (PEG) block confers hydrophilicity. Both ends of the macromer 25 are functionalized with methacrylate groups to allow the copo-26 lymerization with the zwitterionic comonomer. The successful 27 copolymerization was confirmed by infrared spectroscopy with 28 attenuated total reflectance (FTIR-ATR) and X-ray photoelectron 29 spectroscopy (XPS). The copolymerization of MA-PDLLA-PEG-30 PDLLA-MA macromer with CBMAA monomer led to hydrogels 31 with unique properties. On one hand, these hydrogels showed 32 antifouling character-the absence of nonspecific interaction 33 with proteins, but on the other hand, their available carboxyl 34 groups can be utilized for specific immobilization of bioac-35 tive compounds. In order to demonstrate this, the hydrogels 36 were functionalized with fluorescently labeled bovine serum 37 38 albumin (BSA), which was selected as a model protein.

2. Experimental Section

2.1. Materials

3,6-Dimethyl-1,4-dioxane-2,5-dione (D,L-lactide), α,ω -dihydroxy 45 poly(ethylene glycol) (α, ω -dihydroxy PEG) ($\overline{M}_n = 4000 \text{ g mol}^{-1}$), 46 47 tin(II) 2-ethylhexanoate (Sn(Oct)₂) (92.5–100%), methacrylic anhydride (MAAH) (94%), triethylamine (TEA) (≥99%), N-[3-48 (dimethylamino)propyl]methacrylamide (99%), N-hydrox-49 ysulfosuccinimide sodium salt (sulfoNHS) (≥98%), 50 *N*-(3-dimethylaminopropyl)-*N*'-ethylcarbodiimide hydrochloride 51 (EDC), BSA-fluorescein isothiocyanate conjugate (BSA-FITC) 52 were purchased from Sigma-Aldrich. β -Propiolactone was 53 purchased from Serva electrophoresis GmbH. Lucirin TPO-L 54 55 (ethyl-2,4,6-trimethylbenzoyl phenylphosphinate) was acquired from BASF (Germany). Phenol red was supplied by Riedel de 56 Haën. 57

Isopropanol, dichloromethane, diethyl ether, chloroform, 58 tetrahydrofuran, and methanol were purchased from Lachner. 59

Scheme 1. Synthesis of PDLLA-PEG-PDLLA oligomer and MA-PDLLA-PEG-PDLLA-MA macromer.

Tetrahydrofuran (anhydrous THF, ≥99.9%), diethyl ether (anhydrous, \geq 99.7), and phosphate-buffered saline (PBS, pH 7.4) were purchased from Sigma-Aldrich.

33 2.2. Synthesis of MA-PDLLA-PEG-PDLLA-MA Macromer

35 The synthesis of MA-PDLLA-PEG-PDLLA-MA macromer 36 (Scheme 1) was performed in a two-step reaction. In the first 37 step D,L-lactide was polymerized from the hydroxyl end groups 38 of PEG. This was followed by conjugation with methacrylate 39 groups to generate a telechelic macromer.

42 2.2.1. Synthesis of PDLLA-PEG-PDLLA

44 PDLLA-PEG-PDLLA was synthesized by a ring-opening polymerization of D,L-lactide initiated from the terminal 45 hydroxyl groups of α, ω -dihydroxy PEG catalyzed by Sn(Oct)₂ 46 47 (Scheme 1).^[51] The targeted molecular weight of the oligomers 48 was between 4500 and 5000 g mol⁻¹. Firstly, 300 g (75 mmol) 49 of α, ω -dihydroxy PEG was molten and dried in a three-necked 50 flask, under vacuum and magnetic stirring, at 120 °C for

Macromolecular Bioscience www.mbs-iournal.de

10 h. Then 86.5 g (0.6 mol) of D,L-lactide and 0.6 g (1.5 mmol) 1 $Sn(Oct)_2$ was added under argon atmosphere. The molar ratio 2 of D,L-lactide/Sn(Oct)₂ was 400/1. The reaction was carried out 3 for 3.5 h at 140 °C. Afterwards, isopropanol was added to the 4 reaction mixture. This alcohol is a good solvent for the mon-5 omer and catalyst while the polymer precipitates and can be 6 recovered by filtration with copious washing.

2.2.2. Synthesis of MA-PDLLA-PEG-PDLLA-MA Macromer

The oligomer was functionalized with methacrylate groups 12 (MA) by acylation of the terminal hydroxyl groups of the 13 PDLLA-PEG-PDLLA oligomer with MAAH (Scheme 1). Solu-14 tions of PDLLA-PEG-PDLLA ($C = 0.25 \text{ g mL}^{-1}$) and MAAH 15 $(C = 0.2 \text{ g mL}^{-1})$ in dry DCM were prepared in separate flasks 16 and purged with argon for 20 min. Then TEA (18 mL) was 17 injected into the solution of oligomer under argon. The solu- 18 tion of MAAH was added to the solution of oligomer and TEA 19 by dropping funnel. The reaction was allowed to proceed for 20 10 days with continuous stirring. The formed MA-PDLLA- 21 PEG-PDLLA-MA was precipitated into dry diethyl ether and 22 purified by dissolving in chloroform and reprecipitating into 23 diethyl ether.^[52] 24

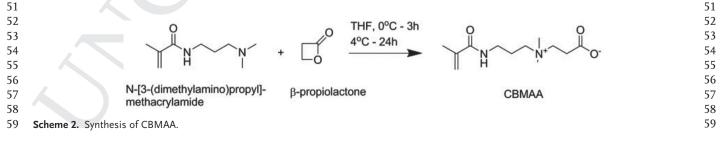

2.3. Synthesis of Carboxybetaine Methacrylamide (3-Methacryloylamino-propyl)-(2-carboxy-ethyl)-dimethyl-ammonium)

CBMAA was synthesized by a modified procedure reported ear-30 lier (Scheme 2).^[53,54] (The synthetic procedure is described in 31 the ESI). 32

2.4. Optimization of the Stereolithography Resin Composition and Building of Hydrogel Structures

Resins of different compositions were prepared (Table 1). The 38 MA-PDLLA-PEG-PDLLA-MA macromer, CBMMA monomer 39 (Table 1) and phenol red dye were dissolved in Milli-Q water to 40 give solution 1. Lucirin TPO-L (visible light photo-initiator) was 41 dissolved in DMSO to give solution 2. Solution 1 and 2 were 42 combined and stirred at room temperature until a clear liquid 43 resin was formed. The final resin composition was: 30 wt% of 44 the mixture of macromer and monomer, 4.95 wt% of Lucirin 45 TPO-L, 0.05 wt% of phenol red, 50 wt% of water and 15 wt% 46 of DMSO. The weight ratio of CBMAA to MA-PDLLA-PEG-47 PDLLA-MA was varied from 0 to 20%. 48

Hydrogels were prepared using Perfactory Mini Multilens 49 stereolithography apparatus (Envision-Tec, Germany) equipped 50

11 with a digital micro-mirror device that enables projections of 1280×1024 pixels, each measuring $32 \times 32 \ \mu\text{m}^2$. Hydrogels 12 with gyroid-type porosity were prepared by the sequential illu-13 mination, polymerization, and cross-linking of layers of the 14 resin. For this, the resin was exposed to a pixel pattern of blue 15 light (wavelength 400-550 nm, peak intensity at 440 nm) while 16 17 the z-position of the platform was moved step-wise (25 µm) 18 to allow the formation of a 3D structure. The gyroid pore structures of hydrogels were designed using Rhinoceros 3D 19 20 (McNeel Europe) and K3DSurf computer software as described 21 elsewhere.^[55]

22 The fabrication of the hydrogel structures was carried out by 23 exposing the photopolymerizable resin to light intensities of $10\ mW\ cm^{-2}.$ The curing time for a $25\text{-}\mu\text{m}\text{-}\text{thick}$ layer was eval-24 25 uated from the working curves obtained for each type of resin 26 formulation-40 s for 0%CBMAA, 54 s for 10%CBMAA and 27 57 s for 20%CBMAA. After photo-polymerization, the obtained structures were washed with acetone (1 day), water (2 days), 28 29 acetone (1 day) to remove any non-cross-linked compounds. The samples were dried at room temperature for 1 day under 30 31 atmospheric pressure and subsequently in vacuum until con-32 stant weight. Flat nonporous samples were also produced for 33 XPS and FTIR analysis.

34 35

36 2.5. Functionalization of Hydrogels with BSA-FITC

37

38 BSA-FITC was covalently immobilized on the pores of the gyroids structures using EDC/sulfoNHS coupling. Hydro-39 gels of each formulation (0% CBMAA, 10% CBMAA, and 40 41 20% CBMAA) were swollen in water and then placed in individual vials containing a solution of EDC (C = 0.522 M) and sul-42 43 foNHS (C = 0.115 M) in water. This solution creates active esters of the CBMAA monomers which can be attacked by amine 44 45 groups of proteins for their covalent immobilization. The samples were shaken for 2 h at room temperature. Subsequently, 46 hydrogels with activated carboxyl groups were washed three 47 48 times with water, allowing at least 20 min for each wash. Then 49 the activated hydrogels were placed to PBS for 1 h. After incu-50 bation, each sample was placed into 4 mL of fresh PBS solution 51 and 2 mL of stock-solution of BSA-FITC ($C = 3.33 \text{ mg mL}^{-1}$) 52 was added. The reaction was allowed to proceed in the dark for 2 h at room temperature and then for 12 h at 4 °C. Finally, the 53 54 hydrogels were thoroughly washed with copious amounts of PBS and stored in this buffer overnight. Confocal imaging was 55 performed after an incubation period of at least one day. 56

57 In order to prove the absence of nonspecific adsorption of BSA-FITC on the hydrogels, blank experiments were per-58 formed. Hydrogels of each formulation were swollen in PBS 59

solution. Then the swollen hydrogels were transferred to vials 1 containing 4 mL of fresh PBS to which 2 mL of stock-solution 2 of BSA-FITC ($C = 3.33 \text{ mg mL}^{-1}$) was added. The incubation 3 time, washing procedures, and imaging were performed as 4 above. 5

2.6. Characterization of Oligomer, Macromer, and Hydrogels

¹H NMR spectra of reaction products were recorded on Bruker 12 DPX 300 and utilized to determine conversion of D,L-lactide, 13 chemical structure, molecular weight of PDLLA-PEG-PDLLA 14 and degree of functionalization with MAAH. CDCl₃ was used 15 as a solvent. 16

2.6.2. Fourier Transform Infrared Spectroscopy with Attenuated Total Reflectance

The chemical structure of synthesized PDLL-PEG-PDLLA oli-22 gomer and MA-PDLLA-PEG-PDLLA-MA-co-CBMAA hydrogels 23 were characterized by FTIR-ATR. Spectra were recorded using 24 an FTIR Thermo Nicolet Nexus 670 spectrometer equipped 25 with a Specac Golden Gate attachment and a diamond reflec-26 27 tion prism.

2.6.3. X-Ray Photoelectron Spectroscopy

31 The chemical composition of the hydrogels was investigated 32 by XPS. The measurements were carried out with a K-Alpha+ 33 spectrometer (Thermo Fisher Scientific). The samples were 34 analyzed using a micro-focused, monochromated Al K α X-ray 35 source (400 µm spot size). The kinetic energy of the electrons 36 was measured using a 180° hemispherical energy analyzer 37 operated in the constant analyzer energy mode (CAE) at 200 eV 38 and 50 eV pass energy for survey and high resolution spectra. 39 Data acquisition and processing were performed using Thermo 40 Advantage software. The XPS spectra were fitted with one or 41 more Voigt profiles (binding energy (BE) uncertainty: \pm 0.2 eV). 42 The analyzer transmission function, Scofield sensitivity fac-43 tors,^[56] and effective attenuation lengths (EALs) for photoelec-44 trons were applied for quantification. EALs were calculated 45 using the standard TPP-2M formalism.^[57] All spectra were ref-46 erenced to the C 1s peak of hydrocarbons at 285.0 eV BE con-47 trolled by means of the well-known photoelectron peaks of PET 48 and metallic Cu, Ag, and Au. 49

2.6.5. Laser Scanning Confocal Microscopy

11 Hydrogels with immobilized BSA-FITC were visualized using 12 the Olympus multiphoton LSCM with the FV10-ASW viewer 13 software (Olympus, Japan). Images were recorded using a 14 4×-air objective and a 488 nm laser for excitation of FITC; emis-15 sion was detected at 500–530 nm. 3D reconstructed images 16 were obtained by stacking 20 LSCM *xy*-scans at 0.5 μ m inter-17 vals using the ImageJ software.

3. Results and Discussion

In this study, we report the preparation of a novel type of zwitterionic functionalizable hydrogels with gyroid pore architecture. These hydrogels were prepared by copolymerization of
macromer (MA-PDLLA-PEG-PDLLA-MA) with the zwitterionic
monomer (CBMAA) utilizing stereolithography.

3.1. Synthesis of PDLLA-PEG-PDLLA Oligomer and MA-PDLLA PEG-PDLLA-MA Macromer

31 32 The PDLLA-PEG-PDLLA oligomer was synthesized by ring-33 opening polymerization of D,I-lactide, initiated by the hydroxyl 34 terminal groups of the PEG chain (Scheme 1). The conversion 35 of D,L-lactide was determined from ¹HNMR spectra of the reac-36 tion mixture (Figure S1, Supporting Information). When the 37 lactide cycle is opened, protons of the methyl groups present 38 in D,L-lactide are shifted from δ 1.64–1.61 to δ 1.60–1.37 ppm. 39 The conversion was calculated as the ratio of the integral of 40 the shifted peaks (δ 1.60–1.37 ppm) to the sum of integrals of 41 shifted peaks and peaks of residual D,L-lactide (δ 1.64–1.61 ppm) 42 (Equation S1, Supporting Information) and was equal to 93%.

A prominent band at 1750 cm⁻¹ in the FTIR-ATR spec-43 44 trum of PDLLA-PEG-PDLLA assigned to ester carbonyl con-45 firms the successful polymerization of D,L-lactide (Figure S2, 46 Supporting Information). On the ¹HNMR spectrum a peak 47 at δ 4.13–4.42 ppm, corresponding to methylene protons of 48 the PEG connected to PDLLA could be discerned proving the 49 structure of PDLLA-PEG-PDLLA (Figures S1 and Figure S3, 50 Supporting Information). The degree of polymerization 51 of D,L-lactide (m) was calculated by comparing the inte-52 grals corresponding to protons of methylene groups of PEG (δ 3.20–3.90 ppm in Figure S3, Supporting Information) and 53 54 protons of methyl lactyl units (δ 1.37–1.60 ppm in Figure S3), 55 considering the average degree of polymerization of PEG is $DP_n = 91$ (Equation S2, Supporting Information). The NMR-56 57 degrees of polymerization were used to calculated the number average molecular weight of PDLLA-PEG-PDLLA oligomer 58 59 $\overline{M}_n = 5250 \text{ g mol}^{-1}$.

The hydroxyl end groups of the synthesized PDLLA-PEG-1 PDLLA oligomer were acylated with MAAH to obtain the MA-2 PDLLA-PEG-PDLLA-MA macromer (Scheme 1). The incor- 3 poration of methacrylate groups to PDLLA-PEG-PDLLA was 4 confirmed by the appearance of three signals in the ¹HNMR 5 spectrum of the macromer: at δ 6.14, 5.58, and 1.90 ppm, cor- 6 responding to the = CH_2 and $-CH_3$ of the methacrylate groups 7 (Figure S4, Supporting Information). The complete disap-8 pearance of the signals of terminal hydroxyls in PDLLA-PEG-9 PDLLA (δ 2.83) indicates that all end-groups contain a meth- 10 acrylate. This was further confirmed by comparing the integrals 11 of protons of the methacrylate group (δ 6.14 and 5.57 ppm) 12 with those of PEG (δ 3.40–3.80 ppm) considering the number-13 average degree of polymerization $(DP_n = 91)$.^[52] 14

3.2. Preparation and Characterization of Hydrogels

A precise control over the cure depth of resin is necessary 19 for fabrication of structures by stereolithography. In order 20 to achieve well defined structures it is necessary to tune the 21 cross-linking depth. The polymerization is initiated from an 22 inverted platform that moves upward to generate each layer. 23 Upon irradiation, only part of the resin, which is at focal plane 24 of the laser beam, is cross-linked. The cross-linked volume 25 must be thick enough so that when the platform moves 26 upwards (away from the focal plane) the next cross-linked 27 volume will be grown from the previously formed structure. 28 On the other hand if the depth of cross-linking is too deep 29 then the structure blurs and the pores close.^[24,58,59] The cure 30 depth is determined by the light energy to which the resin is 31 exposed. This energy can be adjusted by the illumination time 32 or by regulating the light intensity. The relationship between 33 the effective cure depth of the resin and the light irradiation 34 dose can be expressed using Equation (2) derived from the 35 Beer-Lambert law: 36 37

$$C_d = D_p \cdot \ln\left(\frac{E}{E_c}\right) \tag{2} \begin{array}{c} 38\\ 39\\ 40 \end{array}$$

where C_d is cure depth, *E* is the energy of the light to which 41 the resin has been exposed, E_c is the critical energy for curing, 42 which represents the minimum energy level required for crosslinking of the resin, and D_n is the penetration depth. 44

Experimentally, an optimal exposure time is determined 45 by constructing the working curve, a plot of the C_d versus the 46 natural logarithm of the energy ln(E). From the intercept and 47 slope of the working curve, the critical energy E_c and penetra-48 tion depth of light into resin D_p can be determined. The critical 49 exposure and penetration depth are very important parameters 50 and must be evaluated for each resin formulation before the 51 scaffold fabrication to prevent the failure of interlayer bonding 52 or inaccuracies in the architecture.^[52,55] 53

Resins based on MA-PDLLA-PEG-PDLLA-MA with different 54 weight ratio of CBMAA were prepared (Table 1). A 0.05 wt% of 55 phenol red dye was added to each formulation to restrict the 56 penetration depth of the light and gain better control over the 57 layer thickness.^[60] The working curves for all resin composi-58 tions were obtained by varying the energy of the light exposed 59

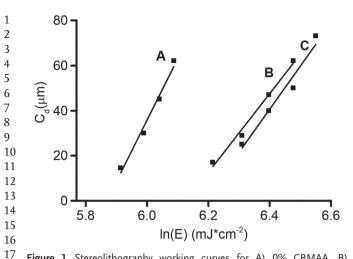

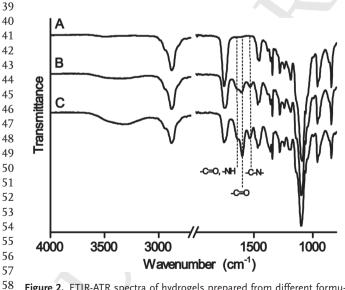

Figure 1. Stereolithography working curves for A) 0% CBMAA, B)
 10% CBMAA, and C) 20% CBMAA resins.

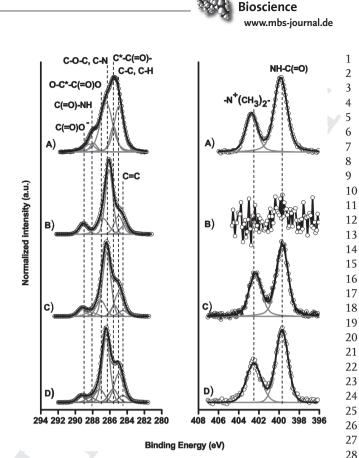

20 at the resin surface (*E*) and measuring the resulting cure 21 depths (C_d) of the resins (**Figure 1**). The required curing times 22 for a 25-µm-thick layer at a light intensity equal to 10 mW cm⁻² 23 were calculated to be 40 s, 54 s, and 57 s for 0% , 10% , and 24 20% CBMAA resins respectively.

25 Nonporous films and hydrogels with gyroid pore archi-26 tecture were fabricated by stereolithogaphy utilizing resins 27 containing different amount of zwitterionic comonomer 28 CBMAA. All hydrogel structures were soft and highly flexible, 29 their shape and structure precisely matched their design. The chemical structure of the hydrogels was confirmed by FTIR-30 31 ATR (Figure 2). The increase in the amount of zwitterionic 32 comonomer was evidenced by the concomitant increase in the intensity of amide bands at 1650 cm⁻¹ and 1535 cm⁻¹, and the 33 34 carboxyl band at 1600 cm⁻¹ arising from the CBMAA added to 35 the resin formulation.

In addition, the chemical composition of hydrogels was
further evidenced using XPS. Figure 3 reports the high
resolution core level C 1s and N 1s regions of spectra of the

Macromolecular

29

32

Figure 3. High resolution C 1s (left) and N 1s (right) XPS spectra of A) pure poly(CBMAA), B) 0%CBMAA, C) 10%CBMAA, and D) 20%CBMAA dry hydrogels.

bulk poly(CBMAA) material and 0%CBMAA, 10%CBMAA, 33 and 20%CBMAA hydrogels. The C 1s spectrum of 34 polv(CBMAA) bulk material is characterized by a C-C con-35 tribution at 285.0 eV, which is accompanied by contribu-36 tions at 285.6 \pm 0.1 eV, 286.2 \pm 0.2 eV, 287.9 \pm 0.1 eV, and 37 288.3 ± 0.1 eV arising from the secondary chemical shift,, that 38 is, the effect of the amide group on the tertiary carbon atom 39 in the CH_3 –C*–C(=O)–NH structure, the C–N⁺ moieties, the 40 amide group C(=O)-NH and the carboxylic (O-C=O) group. 41 The N 1s spectrum of poly(CBMAA) is characterized by contri-42 butions at about 399.5 \pm 0.1 eV and 402.5 \pm 0.1 eV of amides 43 and charged quaternary ammonium groups, respectively. The 44 0%CBMAA hydrogel shows the characteristic contributions for 45 the lactide and ethylene oxide monomers as well as the meth-46 acrylate groups that did not react during the photo-curing reac-47 tion. The contributions centered at 284.5 \pm 0.1 eV, 285.0 eV, 48 286.3 ± 0.2 eV, 287.0 ± 0.2 eV, and 289.0 ± 0.5 eV arise from 49 the C=C, C-C, C-O-C, O-C*-C(=O)O, and ester O-C=O 50 group, respectively. The N 1s spectrum of 0%CBMAA com-51 pletely lacks nitrogen (amides and charged quaternary ammo-52 nium groups) contributions. 53

The incorporation of CBMAA monomer units into the 54 MA-PDLLA-PEG-PDLLA-MA structure is clearly observed in 55 the high resolution C 1s and N 1s spectra of the 10%CBMAA 56 and 20%CBMAA hydrogels. The presence of CBMAA can be 57 verified by the rise of the contributions of C–C at 285.0 eV, 58 $CH_3-C^*-C(=O)-NH$ at 285.6 ± 0.1 eV, the C–N⁺ moieties 59

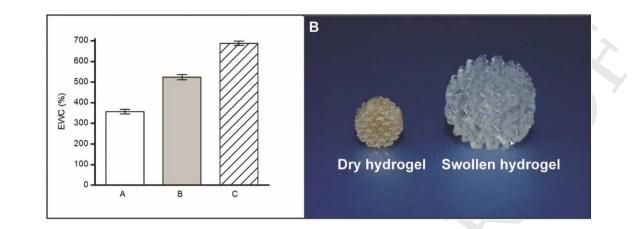

Figure 4. The equilibrium water content (EWC) of hydrogels A) 0% CBMAA, B) 10% CBMAA, and C) 20% CBMAA, defined as the ratio between the mass of absorbed water after reaching the equilibrium and the mass of dried hydrogels (left). The photograph shows dry and swollen hydrogel of 10% CBMAA (right).

20 (which strongly overlap with the $O-C^*-C(=O)O$ contribu-21 tions of PDLLA at 286.3 \pm 0.2 eV) and the C(=O)-NH group 22 at 288.1 \pm 0.2 eV within the C 1s spectra, as well as the occur-23 rence of contributions arising from amide at 399.7 \pm 0.1 eV and 24 charged quaternary ammonium groups at 402.5 \pm 0.1 eV in 25 the high resolution N 1s spectra. The increase of CBMAA in 26 the polymerization feed from 10 to 20% lead to an increase of 27 the nitrogen content from 1.3 at.% to 2.8 at.%.

28 The swelling behavior and water uptake capability are essen-29 tial parameters of scaffolds for tissue engineering. Highly 30 wetted scaffolds provide a good environment for cell growth 31 and proliferation. However, water content of all natural tissues 32 differs depending on the tissue function. Thus, it is of high 33 importance to be able to tune the water content in order to 34 match the properties of targeted tissue. The copolymerization 35 of macromer MA-PDLLA-PEG-PDLLA-MA with zwitterionic 36 comonomer CBMAA can enable tuning the swelling properties 37 of the hydrogels.^[38,39] As expected, an increase in the amount of CBMAA in the polymerization resin lead to an increase of 38 39 EWC of hydrogels (Figure 4). A 50% increase in swelling was observed with the addition of only 10% of CBMAA to the 40 41 polymerization feed. A further increment in the CBMAA con-42 centration to 20% led to hydrogel with remarkable water con-43 tent reaching the value of 700%.

44 45

47

46 3.3. Protein Immobilization on Hydrogel Pores

48 A widely used approach to induce specific cell adhesion is to 49 immobilize biomolecules, such as peptides or proteins, on the 50 surface of the scaffold to interact with integrin receptors of the 51 cell. To immobilize the bioactive compounds, the material of 52 the scaffold must possess available functional groups while preventing any nonspecific interactions that can occur at the interface 53 54 between the biological medium and the surface of the scaffold. To achieve this, CBMAA was introduced as a comonomer for the 55 preparation of hydrogels. It was hypothesized that the copolym-56 57 erization of the macromer with CBMAA will provide not only available carboxylic groups for the biofunctionalization but also 58 59 will ensure the resistance to nonspecific interaction with proteins.

The pores of the hydrogels were functionalized with a flu-20 orescently-labeled model protein, BSA-FITC. For this, carboxy-21 late groups of the carboxybetaine monomers were activated 22 with EDC/sulfoNHS in water, followed by incubation with 23 a protein solution in PBS buffer (Figure 5D-F). To prove the 24 specificity of the binding we performed control experiments by 25 incubating with BSA-FITC for 14 h without any previous acti-26 vation with EDC/sulfoNHS. No fluorescence was observed on 27 nonactivated hydrogels during the scanning of all hydrogels 28 (0%, 10%, and 20%CBMAA) with a 488 nm laser for excitation 29 of FITC proving the absence of nonspecific albumin adsorption 30 on the hydrogels (Figure 5A–C). 31

As expected, no BSA immobilization was observed on 32 the hydrogel without any addition of CBMAA (0%CBMAA) 33 (Figure 5D), due to the lack of functional groups on hydro-34 gels. On the other hand, hydrogels containing 10% and 20% of 35 CBMAA were successfully biofunctionalized with BSA-FITC as 36 presented in Figure 5E,F. These hydrogels show strong fluores-37 cence emission stemming from BSA-FITC. ImageJ software was 38 used to measure the mean average intensity of the pixels in the 39 fluorescent area in order to analyze the difference in the fluo-40 rescence intensity in hydrogels containing 10 and 20%CBMAA. 41 The fluorescence intensity of hydrogels containing 10%CBMAA 42 was 22.8 \pm 4.3 a.u., while that of hydrogels with 20%CBMAA 43 was 33.4 ± 5.0 a.u.; emitting almost 32% more light. The larger 44 fluorescent signal is well in line with the higher amount of func-45 tionalizable carboxylate groups. Figure 5G depicts the 3D recon-46 struction of 20 confocal scans of 10%CBMAA hydrogel after bio-47 functionalization showing that the pores were homogeneously 48 modified all across the structure. 49

4. Conclusions

Stereolithography was utilized to fabricate non-fouling hydrogels with a precisely designed interconnected porosity. The 55 hydrogels were prepared by copolymerization of macromer MA-PDLLA-PEG-PDLLA-MA and CBMAA. The addition of CBMAA 57 comonomer endowed the hydrogels with an increase in EWC, 58 reaching an unprecedented level of 700% for 20%CBMAA. The 59

www.advancedsciencenews.com

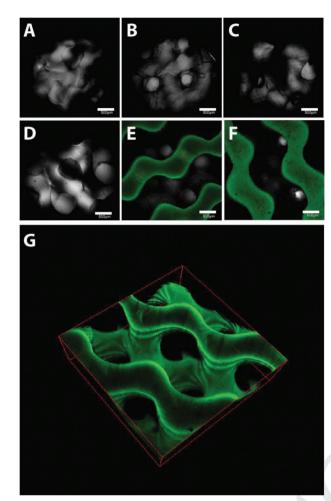

Figure 5. Biofunctionalization of gyroid hydrogels with BSA-FITC observed by confocal laser microscopy. The contact of BSA-FITC with non-activated hydrogels shows no fluorescence (A-C for 0, 10 and 20% CBMAA hydrogels respectively). D-F are confocal images of hydrogels with 0, 10 and 20% of CBMAA preactivated with EDC/sulfoNHS. The strong fluorescence in E and F proves the successful biofunctionalization. Image G represents the 3D reconstruction of 20 confocal xy scans of 10% CBMAA hydrogels with immobilized BSA-FITC.

CBMAA monomers endowed the hydrogels with antifouling properties while biofunctionalizable. The open interconnected porosity allowed the modification of the surface of the pores with proteins as evidenced by LSCM.

The hydrogels described here represent a novel and highly promising scaffold for tissue engineering. The shape and pore 48 architecture of hydrogels can be precisely designed and imple-49 mented by stereolithography. The combination of oligomer 50 based on hydrophilic (PEG) and degradable (PDLLA) segments 51 and a zwitterionic comonomer endows these hydrogels the tun-52 able swelling properties, antifouling character and available func-53 tional groups for the immobilization of bioactive compound.

Please send me and bill me for

no. of **Reprints** via airmail (+ 25 Euro)

Please send me and bill me for a

high-resolution PDF file (330 Euro).

My Email address:

Please note: It is not permitted to present the PDF file on the internet or on company homepages.

Information regarding VAT

Please note that from German sales tax point of view, the charge for **Reprints, Issues or Posters** is considered as "**supply of goods**" and therefore, in general, such delivery is a subject to German sales tax. However, this regulation has no impact on customers located outside of the European Union. Deliveries to customers outside the Community are automatically tax-exempt. Deliveries within the Community to institutional customers outside of Germany are exempted from the German tax (VAT) only if the customer provides the supplier with his/her VAT number. The VAT number (value added tax identification number) is a tax registration number used in the countries of the European Union to identify corporate entities doing business there. It starts with a country code (e.g. FR for France, GB for Great Britain) and follows by numbers.

VAT no.: _

(Institutes / companies in EU countries only)

Editorial Office:

Wiley-VCH Verlag Boschstraße 12, 69469 Weinheim Germany

Tel.: +49 (0) 6201 - 606 - 581 Fax: +49 (0) 6201 - 606 - 510 Email: macromol@wiley-vch.de
