Chick development

ABSTRACT

Regulation of the Bone Morphogenetic Protein (BMP) signaling pathway is essential for the normal development of vertebrate gastrointestinal (GI) tract, but also for the differentiation of the digestive mesenchymal layer into smooth muscles and submucosal layer. Different studies demonstrated that *Bapx1* (for bagpipe homeobox homolog 1) negatively regulates the BMP pathway, but its precise expression pattern during the development and the differentiation of the GI tract mesenchyme actually remains to be examined. Here, we present the spatio-temporal expression profile of *Bapx1* in the chick GI tract. We show that *Bapx1* is first expressed in the undifferentiated mesenchyme of the gizzard and the colon. After the differentiation of the digestive mesenchyme, we found *Bapx1* strongly expressed in the gizzard smooth muscle and in the submucosa layer of the colon. This expression pattern provides new insights into the roles of *Bapx1* during the regionalization of the GI tract and the differentiation of the digestive mesenchyme of the colon and the stomach.

The gastrointestinal (GI) tract is a remarkably complex, three dimensional, specialized and vital organ system derived from a simple tubular structure. The vertebrate GI tract includes the luminal digestive system of the esophagus, stomach, intestines, and colon (which we will designate as “gut”) and the GI tract derivatives – thyroid, lungs, liver, and pancreas (Grapin-Botton, 2005; Roberts, 2000; de Santa Barbara et al., 2002). The gut is composed of the three germ layers – mesoderm (which forms the smooth muscle layer), endoderm (which forms the epithelial lining), and ectoderm (which includes the enteric nervous system). Originally, the gut develops from two meso-endodermal invaginations at the anterior (anterior intestinal portal, AIP) and posterior (caudal intestinal portal, CIP) end of the embryo, which elongate and fuse to form a straight tube. This primitive gut tube is initially patterned into three broad domains along its anterior-posterior (AP) axis: the fore-, mid- and hindgut. As they develop, each region of the gut acquires mesodermal and endodermal morphologies, which can be easily discerned by gross and microscopic examination. These tissues differentiate in a regionally specific pattern of differentiation along the AP axis, designating the pharynx, esophagus, and stomach (the foregut), small intestines (the midgut), and large intestines (hindgut). In addition to this AP axis differentiation, the digestive mesenchyme differentiates along the radial axis and

gives rise to the submucosa and smooth muscle layers (Faure and de Santa Barbara, 2011).

Candidate factors for GI mesoderm regionalization include nuclear transcription factors (as Hox and Nkx factors) and secreted factors (such as Hedgehog ligands) (de Santa Barbara and Roberts, 2002; Smith et al., 2000; Ramalho-Santos et al., 2000). Bone morphogenetic proteins (BMP) are secreted signaling molecules that belong to the Transforming Growth Factor β (TGF β) superfamily. BMP ligands were initially identified as key regulators of bone formation (Urist et al., 1979), but subsequent analyses have demonstrated that these ligands regulate a spectrum of developmental processes throughout embryogenesis and organogenesis (reviewed in Hogan (1996); de Santa Barbara et al., 2003). Early during GI development, *Bmp4* is expressed in the mesenchyme of the entire gut exclusive of the gizzard (Roberts et al., 1998). When misexpressed in the gizzard, *Bmp4* induces an upregulation of the pyloric sphincter marker *Nkx2.5* in the posterior gizzard mesoderm (Smith and Tabin, 1999; Smith et al., 2000). These experiments indicate that a low level of BMP signaling activity is a prerequisite for the correct regionalization of the stomach. Out of the candidate genes for regulating BMP signaling during GI tract development in the chick embryo is the homeotic gene *Bapx1* (also named *Nkx3.2*). *Bapx1* expression has been reported for the vertebrate stomach (Nielsen et al., 2001; Akazawa et al., 2000; Verzi et al., 2009). In chick, *Bapx1* is expressed early during development in the gizzard mesenchyme but not in the proventriculus (Nielsen et al., 2001). Ectopic expression of *Bapx1* in the proventriculus results in a gizzard-like morphology and inhibits normal proventricular

expression of *Bmp4*, strongly suggesting a role for *Bapx1* in the regionalization of the chick stomach through the control of *Bmp4* expression (Nielsen et al., 2001; de Santa Barbara et al., 2005). In addition, it has been shown that when *Bmp4* is misexpressed in the gizzard mesoderm, smooth muscle differentiation is impaired (Smith et al., 2000; de Santa Barbara et al., 2005). A regulated level of BMP signaling activity is then a prerequisite for normal development and differentiation of the gizzard mesenchyme (de Santa Barbara et al., 2005; Notarnicola et al., 2012). Although it has been shown that the ectopic expression of *Bapx1* causes a marked muscular hypertrophy (Nielsen et al., 2001; de Santa Barbara et al., 2005), its expression profile during the differentiation of the mesenchymal layer into smooth muscle and submucosa remains to be examined.

The goal of this study was to analyze the endogenous expression pattern of *Bapx1* during the process of smooth muscle differentiation, from E4 to E9, in the developing chick GI tract.

1. Results

1.1. *Bapx1* expression in E4 chick GI tract

In order to investigate the expression pattern of *Bapx1* during the development of the digestive tract, we first performed whole mount *in situ* hybridization analyses on 4-day-old dissected guts (E4 or stages 23–24) and observed that *Bapx1* is expressed at high level in the stomach and the colon (Fig. 1A, C and E). Moreover, *in situ* hybridization analyses performed on paraffin sections revealed that *Bapx1* expression is localized in the whole mesenchyme of the stomach and the colon (Fig. 1D and F). At these stages, the primitive gut presents no morphological differences along the anteroposterior axis. The whole digestive mesenchyme is undifferentiated as demonstrated by the absence of *Sm22* expression, a specific differentiated smooth muscle cell marker (Fig. 1B). All together, these data demonstrate that *Bapx1* is expressed at early stages of GI development. Its expression is localized in the mesenchyme of the stomach and the colon before their differentiation into smooth muscle.

1.2. *Bapx1* expression in E7 chick GI tract

At E7 (Stage 31), the chick GI tract is regionalized into the stomach, the small intestine and the colon. Intestine and colon are separated by the bilateral caeca. The stomach is composed of two structures: the gizzard and the proventriculus, respectively the muscular and glandular stomach (Fig. 2A). At this stage, the mesenchyme of the GI tract is differentiated in smooth muscle as demonstrated by *Sm22* staining uniformly localized into the GI musculature with the exception of the caeca and the two intermuscular tendons present in the stomach (Le Guen et al., 2009) (Fig. 2B). Whole-mount *in situ* hybridization analyses performed at this stage revealed a high level of *Bapx1* expression in the gizzard (Fig. 2C and D). A strong expression of *Bapx1* was also detected in the pylorus, a structure that allows the connection of the stomach to the duodenum (Fig. 2C). Immunostaining on paraffin sections indicated that at this stage, the mesenchyme of the stomach is differentiated along the radial axis into submucosa (negative for the specific alpha Smooth Muscle Actin marker (α SMA)) and smooth muscle (positive for α SMA) layers. The enteric nervous system precursors (positive for HNK-1), organized in myenteric plexi, are localized in the outer part of the smooth muscle domain (Fig. 2E and H). Comparison of *Bapx1* *in situ* staining to α SMA/HNK-1 immunostainings performed on adjacent longitudinal sections indicated that *Bapx1* is highly expressed in smooth muscle cells in the gizzard (Fig. 2F; compare Fig. 2G and

H). In addition, a faint expression of *Bapx1* was also detected in the α SMA-negative submucosa layer. In the smooth muscle domain, *Bapx1* expression was not detected in the plexi (Fig. 2G). At E7, the colon smooth muscle is well differentiated, as demonstrated by the expression of α SMA on paraffin sections (Fig. 2I). We found that *Bapx1* is highly expressed in the colon (Fig. 2C, D and J). Interestingly, its expression is lower in the posterior part of the colon and even almost no detectable in the rectum (Fig. 2J). Analyses of *Bapx1* staining on paraffin sections revealed that *Bapx1* is localized in the submucosa layer with a higher level in cells of the submucosa layer bordering with the epithelium and the smooth muscle domain (compare Fig. 2I–K). These observations are confirmed by simultaneous *in situ* hybridization with *Bapx1* coupled to immunofluorescence with α SMA analyses on the same colonic section (Fig. 2L).

1.3. *Bapx1* expression in E9 chick GI tract

Whole-mount *in situ* hybridization analyses performed at E9 (Stage 35) revealed *Bapx1* expression in the gizzard, the pylorus and the colon. No expression was detectable in the rectum (Fig. 3A and B). At this stage, we observed a new area of expression in the whole small intestine (see arrowhead Fig. 3A). As previously observed at earlier stages (see Fig. 2), the expression of *Bapx1* in the gizzard is high and localized in the smooth muscle layers (compare Fig. 3C and D). A very faint staining was also detected in the submucosa layer (see magnified views in Fig. 3E and F). More posteriorly, we found that all smooth muscle layers (longitudinal, circular and oblique) are positive for *Bapx1* (compare Fig. 3G and H). The expression of *Bapx1* was also observed in the colon (Fig. 3I). At this stage, the colon harbors two α SMA positive smooth muscle cell domains that constitute, from outer to inner, the longitudinal and circular smooth muscle layers. The enteric neural crest precursors, positive for HNK-1, are organized into myenteric and submucosal plexi (shown respectively by white and red arrowheads in Fig. 3J). Comparison of *Bapx1* *in situ* staining to α SMA/HNK-1 immunostainings performed on adjacent longitudinal sections revealed that *Bapx1* is expressed both in the submucosa and the smooth muscle layers, with a stronger expression in cells located at the junction between these two domains (compare Fig. 3J and K). Interestingly, we observed that the width of *Bapx1* expression domain in the smooth muscle decreases along the AP axis of the colon (Fig. 3I). Only a stripe of *Bapx1* expression was found in a group of cells bordering the submucosa layer at the transition between colon and rectum (compare Fig. 3L and M) consistent with the absence of *Bapx1* expression observed in the rectum (arrows in Fig. 3B). In the small intestine, the expression of *Bapx1* is mainly localized in the submucosa layer and in the outer part of the undifferentiated intestinal mesenchyme (see respectively black and white arrows, Fig. 3N and O). These observations are confirmed by simultaneous *in situ* hybridization with *Bapx1* coupled to immunofluorescence with α SMA analyses on the same section (Fig. 3P). Interestingly, no expression was detectable in the intestinal smooth muscle (compare Fig. 3N–P).

2. Discussion

It was previously shown that a low level of BMP signaling activity is a prerequisite for normal development and differentiation of the digestive mesenchyme (Roberts et al., 1998; Smith et al., 2000; de Santa Barbara et al., 2005; Notarnicola et al., 2012). A candidate gene for regulating BMP signaling during GI tract development in the chick embryo is the homeotic gene *Bapx1* (or *Nkx3.2*) (Nielsen et al., 2001). Both gain-and loss-of *Bapx1* functions have suggested a role for this gene in regulating the expression and patterning of

Bmp4 in the chick stomach (Nielsen et al., 2001). In this study, we report the endogenous expression pattern of *Bapx1* during the chick GI tract development and digestive smooth muscle differentiation.

We found that *Bapx1* is expressed in the mesenchyme of the gizzard during the early stages of GI development and that its expression is maintained in the mesenchyme during its differentiation into smooth muscle. Later on, *Bapx1* expression is localized in all the smooth muscle layers (longitudinal, circular and oblique) of the gizzard. The expression of *Bapx1* in the smooth muscle of the stomach is maintained during development as we observed its expression at E18 (data not shown), when the digestive musculature is functional (Notarnicola et al., 2012).

In addition, we found an unexpected expression of *Bapx1* in the pylorus, a conserved structure that connects the stomach to the duodenum. The development of the pyloric structure is controlled by the activity of the BMP signaling pathway (Smith and Tabin, 1999; Smith et al., 2000; Moniot et al., 2004). It has been reported that a sustained expression of *Bapx1* in the pylorus induces a hypertrophic pyloric sphincter, highly related to the Infantile Hypertrophic Syndrome observed in humans (Roberts et al., 1998; de Santa Barbara et al., 2002, 2005; Smith and Tabin, 1999; Moniot et al., 2004). Taken together, these results suggest

that the endogenous expression of *Bapx1* has to be tightly regulated during the development of this structure.

In this study, we also report an early expression of *Bapx1* in the colonic mesenchyme. This observation is unexpected, as it has been shown that *Bmp4* is strongly expressed in the colon at this early stage of GI tract development (Roberts et al., 1998; Smith et al., 2000; our unpublished results). Later during the differentiation of the colonic mesenchyme, *Bapx1* is highly expressed in the submucosa layer, a domain composed of loose cells that express numerous extracellular matrix proteins such as laminin and fibronectin (Simon-Assmann et al., 1994). To our knowledge, *Bapx1* is the first transcription factor described so far to be expressed in the submucosa layer of the colon. At later stage (E9), *Bapx1* is expressed in the smooth muscle and the submucosa layer of the colon. Interestingly, we observed a gradient of *Bapx1* expression along the AP axis in the colonic smooth muscle. Posteriorly, only a stripe of *Bapx1* expression was found in the smooth muscle, in a group of cells bordering the submucosa layer. The expression of *Bapx1* in the inner-most part of the muscle layer in the colon was also observed at E18 (data not shown).

All together, our study provides new perspectives concerning the roles of *Bapx1* during the development and differentiation of digestive musculature.

3. Experimental procedures

3.1. Chick embryos

Timed fertilized white Leghorn eggs (Haas Farm, France) were incubated at 38 °C in a humidified incubator (Coudelou, France) until used experimentally. Embryos were staged according to [Hamburger and Hamilton \(1951\)](#) by embryonic day (E) for gastrointestinal tract analysis. Dissected gastrointestinal tissues were fixed in 4% paraformaldehyde for 1 h at room temperature, washed in PBS, gradually dehydrated in Methanol in order to store the samples at -20 °C before processing for whole-mount *in situ* hybridization as described below ([Faure et al., 2002](#)).

3.2. Whole-Mount *in situ* hybridization

Whole-mount *in situ* hybridization analyses were carried out as described by [Moniot et al. \(2004\)](#) using antisense *Bapx1* ([Nielsen et al., 2001](#)) and *Sm22* riboprobes. Chick *Sm22* cDNA was isolated, sequenced and used to prepare riboprobes for *in situ* hybridization using specific primer pair of chick *Sm22* (Gene Bank ID: NM_205494.1; forward: 5'-TGA GCA GGG ATG TCC AGT -3', reverse: 5'-AGC CAA TGA TGT TCT TGC C-3' generated a 501 bp

fragment cloned into the pGEMT-Easy plasmid (Invitrogen). Tissues were gradually rehydrated in PBS, washed in PBT (PBS, 0.1% Tween) and incubated for 1 h in 6% hydrogen peroxide (Sigma, France). Samples were next permeabilized by treatment with proteinase K (10 μ g/ml) for 10 min, washed with glycine in PBT and fixed in 4% paraformaldehyde/0.2% glutaraldehyde in PBT for 20 min. Tissues were then hybridized with antisense *Bapx1* or *Sm22* digoxigenin-labelled (Roche) riboprobes overnight at 70 °C. After post-hybridization washes at 70 °C, tissues were incubated in 10% sheep serum for 2.5 h at room temperature and finally mixed with preabsorbed anti-digoxigenin coupled with alkaline phosphatase antibody (Roche) overnight at 4 °C. The complexes were detected with BM purple solution (Roche).

3.3. Immunohistochemistry and *in situ* hybridization on paraffin sections

For sectioning, tissues were first gradually dehydrated in Ethanol, incubated in HistoClear solution (VWR, France) and finally embedded in Paraffin. Samples were sectioned at 10- μ m using a microtome and collected on Polysine coated-slides (Thermo Fisher). *In situ* hybridization experiments on paraffin sections were carried out as previously described ([Moniot et al., 2004](#)) using antisense *Bapx1* riboprobes ([Nielsen et al., 2001](#)). Immunofluorescence

Fig. 3. *Bapx1* expression in E9 chick GI tract. (A and B) Whole mount *in situ* hybridization analysis of *Bapx1*. Ventral (A) and dorsal (B) views. *Bapx1* expression is maintained in the gizzard and colon. At this stage, its expression is also detected in the small intestine (arrowhead). Note that its expression is low in the caecum and undetectable in the rectum (arrow). (C) Immunofluorescence analysis performed on longitudinal paraffin sections using anti- α SMA and anti-HNK-1 antibodies showing respectively digestive smooth muscle cells (red) and enteric nervous cell precursors organized in myenteric plexi (green). (D) *In situ* hybridization analysis of *Bapx1* expression directly performed on adjacent longitudinal sections. In the gizzard, *Bapx1* is highly expressed in the smooth muscle domain. (E) Magnified view of the stomach shown in D (black arrow) showing the expression of *Bapx1* in the smooth muscle cells. A faint signal was also detected in the submucosa layer. (F) Magnified view of the stomach shown in C (white arrow). (G) Magnified view of the stomach shown in D (black arrowhead) showing the expression of *Bapx1* in the smooth muscle cells in the longitudinal, circular and oblique layers. (H) Magnified view of the stomach shown in C at the level of the white arrowhead. (I) *In situ* hybridization analysis of *Bapx1* expression directly performed on longitudinal sections. In the colon, *Bapx1* is highly expressed in the mesenchymal derivate layer. (J) Immunofluorescence analyses on longitudinal paraffin sections using anti- α SMA and anti-HNK-1 antibodies showing respectively digestive smooth muscle cells (red) and enteric nervous cell precursors organized in myenteric and submucosal plexi (shown respectively by white and red arrowheads). Red arrow indicates the epithelium layer. (K) Magnified view of the colon shown in I (black arrow). Note the high level of *Bapx1* expression at the junction between the submucosa and the smooth muscle layers (black arrowhead). (L) Immunofluorescence analyses on longitudinal paraffin sections of the colon using anti- α SMA and anti-HNK-1 antibodies. (M) Magnified view of the colon shown in I focusing on the transition between the colon and the rectum (white arrow indicates smooth muscle). (N) *In situ* hybridization analysis of *Bapx1* expression on paraffin sections. In the intestine, *Bapx1* is highly expressed in the mesenchymal derivate layer (black and white arrows). (O) Magnified view of the intestine shown in N showing the expression of *Bapx1* in the submucosa layer (black arrow) and in the outer part of the undifferentiated intestinal mesenchyme (white arrow). (P) Paraffin section processed for both *in situ* hybridization (using *Bapx1* riboprobe) and immunofluorescence (using anti- α SMA antibody) analyses. In the small intestine, *Bapx1* is expressed in the undifferentiated intestinal mesenchyme (submucosa layer and outer part of the intestinal mesenchyme). Abbreviations: c, circular layer; cae, caecum; co, colon; e, epithelium; gz, gizzard; l, longitudinal layer; m, smooth muscle layer; o, oblique layer; pv, proventriculus; py, pylorus; sm, submucosa layer.

studies were performed on paraffin sections using polyclonal antibodies against α SMA (Sigma-Aldrich) and HNK-1 (NeoMarker). Nuclei were labelled with Hoescht (Invitrogene).

3.4. Photography

Images of whole-mount GI tract staining were acquired using a Nikon-AZ100. Images of sections were acquired using a Nikon AZ100 microscope.
