#### **Brief Summary:**

A wide testing strategy is effective in detecting asymptomatic COVID-19 residents and HCP in a NH facing COVID-19 outbreak. Symptomatic residents and HCP as well as asymptomatic HCP with negative testing may also play a role in the virus spread within the NH.

Acknowledgements – The authors thank Anna Bedbrook for editorial assistance and all residents and health care personnel of the nursing home.

#### Abstract

- 4 **Objective:** To assess the American Testing Guidance for Nursing Homes (NHs) updated
- 5 May 19, 2020 with a new COVID-19 case.
- 6 **Design:** Case investigation.
- 7 **Setting and Subjects:** All 79 residents and 34 Health Care Personnel (HCP) of a NH.
- 8 Methods: 7 days after identification of a COVID-19 resident, all residents and HCP
- 9 underwent rRT-PCR testing for SARS-CoV-2 with nasopharyngeal swabs. This was repeated
- weekly in all previously negative subjects until the testing identified no new cases and in all
- positive subjects until the testing was negative. COVID-19 infection prevention and control
- 12 (IPC) measures were implemented in all residents and HCP with positive testing or with
- 13 COVID-19 symptoms. Standard IPC was also implemented in all HCP. Six weeks after initial
- 14 testing, all residents underwent testing for ELISA-based IgG antibodies directed against the
- 15 SARS-CoV-2. Symptoms were serially recorded in residents and HCP.
- 16 **Results:** 36 residents had a positive RT-PCR at baseline and two at day 7. Six HCP had a
- 17 positive RT-PCR at baseline and two at day 7. No new COVID-19 cases were diagnosed
- later. Among the SARS-CoV-2-positive cases, six residents (16%) and three HCP (37%) were
- asymptomatic during the 14 days before testing. Twenty-five residents (92.3%) and all 8 HCP
- 20 (100%) with a positive RT-PCR developed IgG antibodies against SARS-CoV-2. Among the
- 21 residents and HCP always having tested negative, 2 (5%) and 5 (11.5%) developed IgG
- 22 antibodies against SARS-CoV-2. These 2 residents had typical COVID-19 symptoms before
- and after testing and 2/5 HCP were asymptomatic before and after testing.
- 24 Conclusions and Implications: This study shows the validity of the updated American
- 25 Testing Guidance for Nursing Homes (NHs). It suggests implementing COVID-19 IPC in
- 26 both residents and HCP with positive testing or COVID-19 symptoms and warns that
- 27 asymptomatic HCP with repeated negative RT-PCR testing can develop antibodies against
- 28 SARS-CoV-2.

29

30 **Key words:** COVID-19, nursing home, rRT-PCR, antibodies against SARS-CoV-2

#### 31 **Introduction**

- 32 After identification of a COVID-19 case in a Nursing Home (NH), residents are at high risk
- of serious illness and death from COVID-19, with a rapid and widespread transmission of

- 34 SARS-CoV-2. 1,2 The standard COVID-19 diagnosis is based on SARS-CoV-2 nucleic acid
- 35 testing by real-time reverse-transcriptase polymerase chain reaction (RT-PCR).<sup>3</sup> Residents
- and health care personnel (HCP) with positive RT-PCR can be asymptomatic at the time of
- 37 testing and may contribute to transmission.<sup>2</sup> Control strategies focusing only on symptomatic
- 38 residents are therefore insufficient. This explains why the recent American Testing Guidance
- 39 for Nursing Homes recommends (i) testing of all residents and HCP in the NH if there is a
- 40 confirmed case of COVID-19 and (ii) repeated weekly testing of all previously negative
- 41 residents until no new cases of COVID-19 are detected for at least 14 days since the most
- 42 recent positive result. 4
- 43 Seroconversion with SARS-CoV-2 antibodies generally occurs rapidly in adult subjects.<sup>5</sup> The
- 44 immune response to viruses may be influenced by aging, and seroconversion in frail older
- subjects is uncertain. It is unclear whether residents and HCP with repeated negative testing
- 46 may develop antibodies against SARS-CoV-2.
- 47 A study was carried out on all residents and HCP of a NH facing a COVID-19 outbreak. The
- 48 aim was to assess clinical and serological parameters for the efficacy of infection prevention
- and control (IPC) measures adapted to (i) symptoms and (ii) results of repeated testing.

#### 50 **Methods**

- 51 **Setting:** Single NH
- Participants: From March 3<sup>rd</sup> to 6<sup>th</sup>, 2020, three NH residents were hospitalized for severe
- 53 non-respiratory COVID-19 symptoms. All three developed respiratory symptoms (cough with
- fever and dyspnea) 7 to 10 days after admission, and RT-PCR following nasopharyngeal swab
- 55 test confirmed COVID-19. Seven days after the first diagnosis, all residents or HCP were
- 56 enrolled in the study.
- No ethics committee was required as this is an observational study.

58

- Outcomes: COVID-19 symptoms were examined for 14 days before the first test and then
- 60 followed daily for 6 weeks.

- Nasopharyngeal testing for SARS-CoV-2 using rRT-PCR was performed in all residents and
- 62 HCP. It was repeated weekly in all previously negative subjects until no new cases were
- 63 identified and in all positive subjects until testing was negative.
- 64 COVID-19 IPC measures were applied in all residents and HCP with positive testing or with
- 65 new COVID-19 symptoms, including diarrhoea, delirium, or falls.
- 66 Six weeks after initial testing, all residents and HCP underwent blood testing for IgG
- antibodies directed against the SARS-CoV-2 nucleocapsid protein using an ELISA CE-IVD
- 68 marked kit (ID screen® SARS-CoV-2-N IgG indirect ID. Vet, Montpellier, France).<sup>5</sup>

#### Results

69

#### 70 Residents

- Among the 79 residents, 38 (48%) had a positive RT-PCR (Table 1). 36 were diagnosed at
- baseline and two at day 7. The residents who tested positive were distributed throughout the
- 73 4 floors of the NH (10, 9, 10, 9).
- 74 The mean age of residents was similar in positive and negative RT-PCR groups. Diabetes and
- 75 renal disease were more common in RT-PCR positive residents.
- 76 Thirteen residents died two to seven days after testing due to respiratory symptoms. Twelve
- 77 (7 men) had a positive RT-PCR. Six RT-PCR-positive residents (16%) were asymptomatic
- 78 before testing.
- 79 Six weeks after initial testing, seven residents still had at least one typical COVID-19
- symptom (particularly fever or cough) or a significant functional impairment. Among them, 5
- 81 (83%) were RT-PCR-positive.
- The RT-PCR test became negative 14, 21, or 28 days after initial positive testing in 2 (14%),
- 7 (27%), and 12 (46%) residents. In the 5 (19%) who still had positive RT-PCR 28 days after
- 84 initial testing, one recovered completely and 4 had long-lasting symptoms (fever and
- 85 hypothermia; shortness of breath; dry cough; impaired health status).

#### **Health Care Personnel**

- 87 Among the 34 HCP, 6 had positive RT-PCR at baseline and 2 at day 7 (23.5%). No new
- 88 COVID-19 diagnosis was made later. Two thirds of the positive RT-PCR HCP had COVID-
- 89 19 symptoms, often mild.

#### Seroconversion

90

95

- 91 Six weeks after nasopharyngeal testing, 25 residents (92.3%) and all 8 HCP (100%) with
- 92 positive RT-PCR developed SARS-CoV-2 IgG antibodies. Two (5%) RT-PCR negative
- 93 residents and 5 (11.5%) RT-PCR negative HCP developed antibodies. All 2 residents and 3/5
- 94 HCPs had typical COVID-19 symptoms.

#### Discussion

- 96 The present study shows the clinical efficacy of a symptom- and repeated testing-based
- 97 strategy in a NH facing a COVID-19 outbreak. This experience validates the American
- 98 Testing Guidance for Nursing Homes updated in May 2020.<sup>4</sup>
- 99 All residents and HCP were tested and there was no selection bias. This study was conducted
- 100 before any other COVID-19 cases had been detected in the county. The presence of
- antibodies in residents and HCP is therefore almost certainly linked with the COVID-19
- outbreak in that NH.
- In the present study, 16% of residents and one third of HCP with positive RT-PCR were
- asymptomatic in the 14 days before testing. This confirms that all residents and HCP should
- be tested if there is a confirmed case of COVID-19, whatever the symptoms. Two residents
- and two HCP who tested negative at baseline were tested positive for COVID-19 7 days after
- baseline. This suggests that a repeated weekly testing of all previously negative residents and
- HCP until no new COVID-19 cases are identified is also essential in preventing the SARS-
- 109 CoV-2 spread.<sup>4</sup>
- Positive RT-PCR was associated with a severe prognosis (death in 32%), especially in men
- (death in 58%), confirming previous studies.<sup>1,2</sup> Among the 22 negative RT-PCR residents
- presenting COVID-19 symptoms, one died and the others recovered completely, suggesting
- that severe COVID-19 outcomes could be generally, but not always, predicted by positive
- 114 testing.

115 Testing remained positive for 3 weeks or more in two thirds of the RT-PCR positive residents. 116 One remained positive for 8 weeks, indicating that NHs facing a COVID-19 outbreak should 117 be prepared to maintain prolonged protective measures in residents tested positive for SARS-118 CoV-2. In accordance with our regional guidelines<sup>6</sup>, this NH was considered to be COVID-19-free when none of the residents and HCP were diagnosed within the 14 days after the last 119 120 positive result. COVID-19 free NHs apply regional recommended measures to prevent any 121 further COVID entrance and spread. In our Occitanie region, these measures include<sup>6</sup>: 1. 122 Checking that RT-PCR testing in HCP and visitors with COVID-19 symptoms or in those 123 having had contact with COVID-19 suspected or confirmed cases (daily screening) is 124 negative before entering the premises. 2. Checking that RT-PCR testing in all new residents 125 and in all residents having spent more than 24 h outside the NH (especially after 126 hospitalization) is negative before entering. 3. Checking that residents, HCP, and visitors 127 previously tested positive for COVID-19 meet all 3 follow-up NH entrance criteria: (i) 128 resolution of fever (without use of fever-reducing medications) and of other COVID-19 129 symptoms within the past 48 hours; (ii) two consecutive negative RT-PCR results collected 130 ≥24 hours apart, (iii) the first control test collected at least 7 days after the positive testing or 131 7 days after the first COVID-19 symptoms. 4. Obliging visitors allowed to enter the NH to sign a charter in which they agree to adhere to standard and transmission-based precautions to 132 133 prevent COVID-19 spread in the NH (systematic face mask wearing, hand hygiene, and 134 especially social distancing) as well as a registry with contact details to facilitate testing and 135 contact tracing should a new case be diagnosed in the NH. 5. Admission to a private room and 136 14 days of isolation for every new resident and every resident having left the NH for at least 137 24h (especially after hospital stay). 6. Testing of every resident having left the NH for less 138 than 24 hours (especially for medical consultation) 5 to 7 days after a possible contact with 139 COVID-19. 7. Daily screening of all residents for COVID-19 symptoms (including atypical 140 symptoms) and testing if there is any doubt. 8. If regular testing of HCP, visitors, and 141 residents at high risk of encountering COVID-19 subjects outside the NH (health care 142 workers who have a care activity outside the NH, visitors of several NHs, hemodialysed 143 patients, etc...) can be justified in regions with moderate or substantial community 144 transmission, this measure is not recommended in our region in which community 145 transmission is now considered as low.

Residents and HCP with positive RT-PCR developed IgG antibodies against the SARS-CoV-2 in 96% and 100%, respectively, suggesting that most frail older adults living in a NH, as

well as the HCP, can produce an antibody response against SARS-CoV-2.

Two residents (5%) with negative RT-PCR developed antibodies and all had fever or respiratory symptoms consistent with COVID-19 in the 14 days before. This suggests that residents with COVID-19 symptoms should benefit from the same IPC strategy as residents with positive RT-PCR, even if tested negative. Five HCP with negative testing developed antibodies against SARS-CoV-2 (11%) and some of them had no COVID-19 symptoms. This suggests that if specific COVID-19 IPC measures must be implemented in HCP with confirmed or suspected COVID-19, all HCP should wear a facemask, even if asymptomatic and with negative testing.

### **Conclusions and Implications**

The present study supports the recent American testing guidance for NHs. It demonstrates that (i) testing all NH residents and HCP as soon as a new case of COVID-19 is diagnosed and (ii) repeating tests in all previously negative subjects once a week until the testing identifies no new COVID-19 cases is effective in detecting asymptomatic COVID-19 residents and HCP. It also shows that (iii) proposing COVID-19 IPC measures in residents and HCP tested positive or with COVID-19 symptoms and (iv) taking precautions in all other HCP should be

**Conflicts of Interest:** The authors declare no conflicts of interest/Competing interests

effective in blocking the dissemination of the virus in NHs facing a COVID-19 outbreak.
