Introduction

In transitional habitat such as lagoons, fish have to deal with a wide range of changing environmental parameters and therefore a high phenotypic plasticity is beneficial to cope with fluctuating environments. Salinity can rapidly drop in these habitats through freshwater (FW) supplies by rainfalls or rivers. Low-salinity environments can lead to differential distributions of marine species according to their acclimation capacity (Pierce et al., 2012; Wong et al., 1999). Differential habitat distribution has also been observed between individuals within the same species as in stickleback *Gasterosteus aculateus* and in mummichog, *Fundulus heteroclitus*, showing a differential capacity to regulate ions in FW (Scott et al., 2004; McCairns and Bernatchez, 2009). To maintain hydromineral balance in FW environments, fish have to minimise diffusive ion losses and compensate them by actively (re)absorbing ions at the gill and posterior kidney levels (Hickman and Trump, 1969; Dantzler, 1996). The European sea bass, *Dicentrarchus labrax*, is known to undertake seasonal migrations in transitional habitats where salinity fluctuates (Kelley, 1988; Barnabé, 1989; Waldman, 1995). Previous studies highlighted intraspecific differences in FW tolerance in this species at different ages (Giffard-Mena et al., 2008; L'Honoré et al., 2019; Nebel et al., 2005) with about 30% mortality following FW exposure. Fish that did not tolerate FW could survive when they were rechallenged to SW conditions and no intraspecific variation was observed in SW (Giffard-Mena et al., 2008; L'Honoré et al., 2019). In *F. heteroclitus,* Scott et al. (2004) concluded that the divergence in osmoregulatory capacities may result in different capacities to absorb and reabsorb Na^+ and Cl^- at gill and/or kidney levels. In Nebel et al. (2005), it has been suggested that the kidney might be responsible for the osmoregulatory failure detected in FW intolerant fish, linked to a low renal Na^+-K^+-ATPase (NKA) activity and a lower kidney tubular density. In L'Honoré et al., (2019), authors highlighted that intraspecific variation in FW tolerance of European sea bass is supported by strong differences in *nka α1a* expression in the posterior kidney while no difference was measured at the gill level. Authors also showed differences in corticosteroid receptors mRNA levels (*gr1, gr2* and *mr*) with lower expression levels in FW intolerant fish compared to FW tolerant. This suggests an impaired hormonal and stress regulation between both FW-tolerance phenotypes. Pituitary prolactin (PRL) is a key hormone involved in FW acclimation by promoting the maintenance of the hydromineral balance (Hirano 1986; Manzon, 2002; Sakamoto and McCormick, 2006; Breves et al., 2014; Bossus et al., 2017). PRL interacts with PRL receptor (PRLR) to regulate Na^+ efflux, water permeability and the differentiation of ionocytes expressing Na^+/Cl^- cotransporter (NCC) as shown in tilapia and zebrafish (Breves et al., 2013, 2010; Dharmamba et al., 1967; Dharmamba and Maetz, 1972). Prolactin receptors are cell surface receptors known to be expressed in osmoregulatory organs of

49   many teleost species (Manzon, 2002). As for many fish species like *Takifugu rubripes*, two paralogs of *prlr*

50   were identified in *D. labrax* genome called *prlra* and *prlrb* (Lee et al., 2006; Tine et al., 2014). It remains to be

51   determined if both *prlr* paralogs display the same expression pattern according to salinity and if mRNA levels

52   differ between FW-tolerance phenotypes in European sea bass.

53   In fish, blood pH levels are salinity-dependent with lower blood pH at low salinity than in SW as it was

54   demonstrated in European sea bass by Shrivastava et al. (2019). In 8 month-old European sea bass, FW

55   intolerance was characterised by a lower blood osmolality associated with an elevated Na^+/Cl^- ratio, indicating a

56   metabolic alkalosis (L'Honoré et al., 2019). To regulate a high blood pH, fish have to excrete bases as HCO_3^-,

57   mainly associated with Cl^- uptake (Maetz and García Romeu, 1964; Goss and Wood, 1990, 1991; Tresguerres et

58   al., 2006). The apical anion transporters SLC26A6, involved in Cl^-/HCO_3^- and Cl^-/oxalate exchanges, are known

59   to be widespread among species in osmoregulatory organs including the posterior kidney (Mount and Romero,

60   2004; Sardella and Brauner, 2007; Xie et al., 2013; Knauf et al., 2018) and gills (Perry et al., 2009; Boyle et al.,

61   2015) and could be potential entry routes for HCO_3^- in intolerant European sea bass to FW. In the gulf toadfish

62   for example, *slc26a6* was highly expressed in kidney (Grosell et al., 2009) to reabsorb Cl^- from the lumen to the

63   blood. Among three different SLC26 anion transporters in zebrafish (SLC26A6, SLC26A3 and SLC26A4,

64   called *za6*, *za3* and *za4*), *za6* seemed to be the most expressed in gills and was overexpressed when fish were

65   transferred to water with low Cl^- or $NaHCO_3$ (Perry et al., 2009). Moreover, gene knockdown of *slc26a6c*

66   resulted in a reduction in Cl^- uptake in zebrafish larvae confirming the major role of this transporter in Cl^-

67   uptake (Bayaa et al., 2009; Perry et al., 2009). Guh et al. (2015) localised SLC26 genes apically in gill

68   ionocytes, called SLC26 cells, but to our knowledge nothing is known about SLC26 localisation in the fish

69   kidney. In *D. labrax*, the only record about SLC26A6 (most probably SLC26A6c) is very recent and shows a

70   high mRNA expression in the anterior intestine to promote Cl^- transepithelial transport to the blood and HCO_3^-

71   excretion (Alves et al., 2019).

72   The basolateral Na^+/K^+-ATPase (NKA) (Hwang et al., 2011; Kumai and Perry, 2012) is a key player in Na^+ and

73   Cl^- uptake and its importance in FW acclimation has been demonstrated in many fish species (Hiroi et al., 2008;

74   Inokuchi et al., 2008; Watanabe et al., 2008; Hsu et al., 2014; Bollinger et al., 2016). *Nka α1a* transcriptional

75   expression in the posterior kidney was previously shown to be related to FW tolerance in European sea bass

76   (L'Honoré et al., 2019). One other key cotransporter known for Na^+ and Cl^- uptake in fish is the NCC-2A or

77   NCC-like (SLC12A10 or SLC12A10.2), that plays a crucial role in FW acclimation in many fish species

78   including European sea bass (Inokuchi et al., 2008; Wang et al., 2009; Hwang et al., 2011; Blondeau-Bidet et

79 al., 2019). SLC12A10 is localised apically in FW-type branchial ionocytes (*i.e.* NCC-type cells) in several

80 species (Hiroi et al., 2008; Inokuchi et al., 2008; Guh et al., 2015; Blondeau-Bidet et al., 2019). It is highly

81 expressed in FW compared to SW fish gills (Hiroi et al., 2008; Inokuchi et al., 2008; Wang et al., 2009;

82 Blondeau-Bidet et al., 2019). In posterior kidney, *slc12a10.1* paralog has been shown to be highly expressed in

83 zebrafish and in Mozambique tilapia gills compared to other organs (Hiroi et al., 2008; Wang et al., 2009). The

84 Na^+/H^+ exchanger-3 (NHE3) is also localised in the apical membrane of another ionocyte subtype at the gill

85 level (Inokuchi et al., 2008; Watanabe et al., 2008; Hwang et al., 2011; Blondeau-Bidet et al., 2019) and

86 functionally coupled to several other ion transporters facilitating Na^+ uptake (Dymowska et al., 2015). Anion

87 exchanger 1 (AE1) is mainly known to play a role in bicarbonate transport to the blood and Cl^- secretion at the

88 gill and kidney (mammal medullary collecting duct cells) levels (Barone et al., 2004, Lee et al. 2011). AE1 is

89 thought to be functionally linked to apical $V-H^+-ATPase$ (VHA) in order to complete acid secretion. At the gill

90 level, AE1 is localised basolaterally in zebrafish HR cells (Lee et al., 2011). Its role was investigated in medaka

91 *Oryzias latipes* and in zebrafish gills (Lee et al., 2011; Hsu et al., 2014; Liu et al., 2016). In both species, the

92 two analysed paralogs (*ae1a* and *ae1b*) were expressed in gills with *ae1b* being over-expressed in a low-Na^+

93 environment. It has also been suggested that AE1 is involved in Cl^- absorption and HCO_3^- secretion (Evans et

94 al., 2005; Hwang and Lee, 2007; Hwang and Perry, 2010) but its localisation in basolateral membranes of

95 ionocytes in pufferfish *Tetraodon nigroviridis* and in milkfish *Chanos chanos* seems not in favour with this

96 hypothesis (Tang and Lee, 2007; Tang et al., 2011). In European sea bass, no data is available on VHA and AE1

97 localization. VHA mRNA expression and protein activity measurements have shown the presence of VHA in *D.*

98 *labrax* gills in FW media (Sinha et al., 2015; Blondeau-Bidet et al., 2019).

99 Regarding $Na^+/K^+/2Cl^-$ cotransporters (NKCC), three paralogs have been described in teleosts: basolateral

100 NKCC1a mainly expressed in the gills and NKCC1b, both dedicated to NaCl secretion, and the apical NKCC2

101 mainly expressed in the kidney and intestine and attributed to NaCl reabsorption (Haas and Forbush III, 2000;

102 Teranishi et al., 2013). NKCC1 paralogs are expressed in SW-type ionocytes in numerous teleost species

103 including the European sea bass (Lorin-Nebel et al., 2006; Inokuchi et al., 2008; Buhariwalla et al., 2012;

104 Breves et al., 2014). NKCC2 was detected in tilapia and in *D. labrax* intestine (Hiroi et al., 2008; Alves et al.,

105 2019), but there is no data available on its localisation in the gills and in the posterior kidney of *D. labrax*.

106 European sea bass exhibiting a FW intolerant phenotype face a severe hydromineral imbalance and we will

107 analyse if this failure originates from a failure in ion uptake at the kidney and/or gill levels. The involvement of

108 the gill in differential ion uptake capacity of *D. labrax* will be analysed by comparing the expression profile of

109 the main ion transporters in tolerant and intolerant fish to FW. Little information is available about ion

110 transporter expression at the kidney level. This is a first tentative to identify key renal ion transporters in FW

111 kidney and to detect intraspecific differences in the transcriptional profile between tolerant and intolerant fish to

112 FW.

113

114 **Materials and methods**

115   1. Tissue sampling

116 European sea bass juveniles (N=350) were reared at Ifremer Station at Palavas-les-flots (Hérault, France) in

117 recirculating SW (osmolality: 1208 mOsm kg^{-1}, Na^+: 515 mmol L^{-1}, Cl^-: 737 mmol L^{-1}) under a 12/12 hours

118 light/dark photoperiod at 20°C. At the age of 8 months (13.59 ± 0.12 cm, 32.19 ± 2.62 g), 300 fish were then

119 transferred to brackish water (BW; osmolality: 475 mOsm kg^{-1}) for 24h and then transferred to dechlorinated tap

120 FW (osmolality: 8 mOsm kg^{-1}, Na^+: 2 mmol L^{-1}, Cl^-: 3.5 mmol L^{-1}) for two weeks. The 50 remaining fish were

121 transferred from SW to SW as controls. Pellet food (Le Gouessant, France) was proposed to fish daily, but the

122 fish did not feed during the two weeks of FW challenges.

123 Fish were sampled two weeks following FW challenge. FW intolerant fish were identified according to their

124 behavior *e.g.* an atypical swimming (lower velocity sometimes associated with a darker color, isolation from the

125 shoal) as described previously (Nebel et al., 2005; L'Honoré et al., 2019). Fish that did not show any of these

126 traits were considered as FW tolerant fish. In this study we compared three groups: FW tolerant fish (FW_t,

127 N=15), FW intolerant fish (FW_i, N=15), and SW control fish (SW, N=13). After the 2-week FW challenge, fish

128 were killed by a lethal dose of benzocaine (at 100 ppm) and the first left gill arch and the posterior kidney (last

129 posterior third of the excretory kidney) were excised and immerged into RNAlater (Qiagen, Mississauga, ON,

130 Canada) for 24h at 4°C and then stored at -80°C for further analyses.

131 The experiments were conducted according to the guidelines of the European Union (directive 86/609) and of

132 the French law (decree 87/848) regulating animal experimentation. The experimental design has been approved

133 by the French legal requirement concerning welfare of experimental animals (APAFIS permit no. 9045-

134 201701068219555).

135   2. Gene expression

136

2.1 RNA extraction and complementary DNA (cDNA) synthesis

Tissues were thawed on ice in lysis buffer using the total RNA extraction kit (Nucleospin® RNA, Macherey-Nagel, Germany) before performing the extraction. Quantity and purity (A260/280 ratio) of extracted RNA were verified using a spectrophotometer (NanoDrop™ One/OneC Spectrophotometer, Thermo Scientific, Waltham, MA, USA). One microgram of RNA was used to generate the complementary DNA (cDNA) using the qScript™ cDNA SuperMix (Quanta Biosciences™) providing all necessary components for first-strand synthesis: buffer, oligo(dT) primers, random primers and qScript reverse transcriptase.

2.2 Quantification of gene expression levels

384-wells plates were filled with an Echo®525 liquid handling system (Labcyte Inc., San Jose, CA, USA). Each well contained a mix composed by 0.75 µL of LightCycler-FastStart DNA Master SYBR-Green I™ Mix (Roche, Manheim, Germany), 0.037 µL of each primer (forward and reverse primers at 0.2 µM final concentration), 0.21 µL of ultrapure water and 0.5 µL of cDNA. The dilution of the samples was determined according to the standard curves generated for each primer pair. Quantitative real-time PCR (qRT-PCR) was performed using a LightCycler®480 Real-Time PCR System (Roche, Mannheim, Baden-Württemberg, Germany), with the conditions described in Blondeau-Bidet et al., 2019. All the primers used are listed in Table 1. For each organ and gene, efficiency was determined (ranged from 1.8 to 2.1) and was used for gene expression quantification (see below) (Table 1). PCR products were sequenced by Sanger sequencing in order to validate the identity of the amplified sequences in comparison with the sea bass genome. Elongation factor 1 α (*ef1α*) was chosen as a reference gene according to previous studies performed on European sea bass challenged to FW (Nebel et al. 2005; Mitter et al. 2009; Blondeau-Bidet et al. 2016, L'Honoré et al., 2019). Relative expression of the target gene was performed using the delta delta Ct method (Pfaffl, 2001) with the SW condition as the reference condition. Ultra-pure water was used as a negative control template, and each sample was analysed in duplicate.

3. Phylogenetic analysis and protein comparisons

Phylogenetic analyses of *slc26a6* and *nkcc (slc12a1 and slc12a2)* have been performed (Figs 1, 2). Nucleotide sequences from different species were obtained at Ensembl or NCBI (Tables 2, 3). *D. labrax* sequences were obtained from the European sea bass genome project (Tine et al., 2014). Multiple nucleotide alignments were performed with MUSCLE V3.8.31 (Edgar, 2004) and ambiguous regions were removed with Gblocks V0.91b

166 (Talavera and Castresana, 2007). The phylogenetic trees were inferred using the maximum likelihood (ML)

167 method implemented in the PhyML program (v3.1/3.0 aLRT) (Guindon and Gascuel, 2003). Best model of

168 evolution was selected using Modelgenerator V.85 (Keane et al., 2006) following the corrected Akaike

169 Information Criterion (with four discrete gamma categories) and used to construct a phylogenetic tree. Bayesian

170 posterior probabilities were computed with MrBayes 3.2.1 (Huelsenbeck and Ronquist, 2001; Ronquist and

171 Huelsenbeck, 2003). Two different runs with four incrementally heated simultaneous Monte Carlo Markov

172 chains were conducted over one million generations, applying respective substitution models determined for

173 each partition in PartitionFinder2 (Lanfear et al., 2017). Trees were sampled every 100 generations to produce

174 10,000 trees. In order to estimate posterior probabilities, 25% of the trees were discarded as a burn-in stage,

175 observing when average standard deviation of split frequency (ASDSF) values dropped below 0.01. Tree were

176 generated and robustness of the phylogeny assumption was evaluated by bootstrapping procedure from 1000

177 data set replicates and with posterior probabilities (PP). The phylogenetic tree of *slc26a6* was rooted with the

178 *slc26a6* sequences of two reptilians, the Chinese soft-shelled turtle (*Pelodiscus sinensis*) and the painted turtle

179 (*Chrysemys picta bellii*). The phylogenetic tree *of nkcc (slc12a1 and slc12a2)* was rooted with the *ncc3*

180 sequences of the tropical frog (*Xenopus tropicalis*) and the lizard (*Anolis carolinensis*) (Hartmann et al., 2013).

181 Amino acid identities (in %) were performed with MUSCLE V3.8.31 (Edgar, 2004) implemented in Geneious®

182 9.1.8 software (Biomatters).

183   4.   Statistical analysis

184 Analyses were performed using GraphPad Prism (version 6, GraphPad Software Incorporated, La Jolla, CA 268,

185 USA). When parametric conditions were verified, one-way analyses of variances were performed followed by a

186 Tukey's post-hoc test. In the case of non-parametric conditions, a Kruskal-Wallis test was performed followed

187 by a Dunn's post-hoc test. Data are represented as box and whisker plots (from first quartile to third quartile)

188 showing median, minimum and maximum values. Statistical differences were accepted from $P < 0.05$.

189 **Results**

190 Among the 300 fish challenged in FW, 28% of them were detected and characterised as FW intolerant fish and

191 70% as FW tolerant fish.

192   1.   Phylogenetic analysis of European sea bass *slc26a6* and *nkcc* paralogous genes

193   Three paralogs of *slc26a6* have been identified in the European sea bass genome (Tine et al., 2014). The three

194   paralogs are called in this study *slc26a6 a*, *slc26a6 b* and *slc26a6 c* according to their phylogenetic position

195   (Fig. 1) computed by maximum likehood analysis against sequences of selected teleost fish (Table 2).

196   Comparatively, three paralogs were identified in *O. niloticus*, *O. latipes*, *G. aculeatus*, *F. heteroclitus* and in *D.*

197   *rerio* whereas two paralogs were identified in *T. nigroviridis* (a and c clades). The European sea bass *slc26a6*

198   paralogous genes obtained in this study strongly grouped with other teleosts *slc26a6* paralogs. *D. labrax*

199   *slc26a6c* is grouped with *slc26a6c* of *O. niloticus*, *O. latipes*, *T. nigroviridis* and shared 86%, 80% and 56%

200   identity in amino acid sequences respectively. European sea bass SLC26A6c only shares 49% and 54% amino

201   acid identity with its SLC26A6b and SLC26A6a. *Slc26a6b* of *D. labrax* is grouped with *O. niloticus slc26a6b*,

202   sharing 80% identity in amino acid sequences but only 53% with European sea bass SLC26A6a. European sea

203   bass *slc26a6b* is strongly grouped with *O. latipes* and *T. nigroviridis*, sharing 71% and 67% identity in amino

204   acid sequences respectively.

205   Two *slc12a1* (*slc12a1a* and *slc12a1b*) and one *slc12a2* were identified in the European sea bass genome that

206   correspond to NKCC1a, NKCC1b and NKCC2 according to their phylogenetical position (Fig. 2), computed by

207   maximum likehood analysis against sequences of selected teleost fish (Table 3). Three *nkcc* genes were also

208   found in *O. mossambicus*, *O. latipes*, *T. rubripes*, *G. aculeatus* and *G. morhua* while two were found in *T.*

209   *nigroviridis* (1b and 2 clades). European sea bass *nkcc* paralogs strongly grouped with teleost *nkcc* sequences.

210   European sea bass *nkcc1a* and *nkcc1b* are grouped with *O. latipes nkcc1a* and *nkcc1b* and share 90.2% and

211   91.9% identity in amino acid sequences respectively. *D. labrax* NKCC1a and NKCC1b only share 77.8%

212   identity between each other. European sea bass *nkcc2* is strongly grouped with *T. nigroviridis* and shares 82.5%

213   amino acid identity whereas it only shares 57.1 and 55.6% identity with NKCC1a and NKCC1b of European sea

214   bass amino acid sequences.

215   2.   Relative gene expression in osmoregulatory tissues

216   Expression of selected genes was quantified in the gills and in the posterior kidney (Figs 3, 4, 5). Analysed

217   genes were: *ae1a* (*slc4a1-1*), *ae1b* (*slc4a1-2*), *nhe3* (*slc9a3*), *nkcc1a* (*slc12a2*), *nkcc1b* (*slc12a2-like),* *nkcc2*

218   *(slc12a1)*, *vha-b (atp6v1b)*, *ncc1 (slc12a3),* *ncc-2a (slc12a3-like)*, *slc26a6a*, *slc26a6b*, *slc26a6c*, *prlra* and

219   *prlrb*. Among them, *ae1b, slc26a6a, slc26a6b* and *nkcc2* expression levels have not been quantified in the gills.

220   *slc12a2-like* (*nkcc1b*) expression in the gill was below the quantification limit and is therefore not shown in the

221 results. *ae1a* and *nhe3* expression levels have not been quantified in the posterior kidney because their

222 expression was below the quantification limit.

223   2.1 Gill gene expression

224 *ae1a* was not differentially expressed between SW and both FW groups (FW_t and FW_i, Kruskal-Wallis test, $P =$

225 0.13, Fig. 3A). *nkcc1a* expression was significantly lower in both FW phenotypes (FW_t and FW_i) compared to

226 SW (Dunn's test, $P < 0.0001$ and $P = 0.0142$ respectively, Fig. 3B), but no significant differences were

227 measured between FW phenotypes.

228 *nhe3* relative expression showed no significant differences between SW, FW_t and FW_i, (Kruskal-Wallis test, $P =$

229 0.1081, Fig. 3C) but a higher variability was observed in FW conditions. *vha-b* expression levels were

230 significantly higher in SW than in both FW phenotypes (FW_t and FW_i), but no differences were measured

231 between FW_t and FW_i (Dunn's test, $P < 0.0001$, $P = 0.0007$ and $P = 0.9215$ respectively, Fig. 3D). No

232 significant differences have been measured for *ncc1* expression levels between the three groups (Kruskal-Wallis

233 test, $P = 0.0626$, Fig. 3E), but there is more variability in FW_i compared to SW and FW_t, with an almost

234 significant difference between FW_t and FW_i (Dunn's test, $P = 0.0676$). *ncc-2a* expression was significantly

235 higher in FW_t than in SW (Dunn's test, $P = 0.0170$, Fig. 3F), but no differences were measured between SW and

236 FW_i as between FW_t and FW_i (Dunn's test, $P = 0.0562$ and $P > 0.9999$ respectively). Among *slc26a6* paralogs,

237 only *slc26a6c* expression has been detected in the gills. FW_t exhibited a significantly lower expression of

238 *slc26a6c* compared to both SW and FW_i (Dunn's test, $P = 0.0309$ and $P = 0.0367$, Fig. 3G) whereas no

239 difference was observed between SW and FW_i (Dunn's test, $P > 0.9999$).

240 Prolactin receptor *prlra* relative expression was significantly higher in FW_i compared to SW fish (Dunn's test P

241 $= 0.0001$, Fig. 5A). No difference in *prlra* expression was recorded between SW and FW_t or between FW_i and

242 FW_t (Dunn's test, $P = 0.1324$ and $P = 0.0652$ respectively) but a high variability is observed in FW_i. *Prlrb*

243 expression was lower in FW groups compared to SW, but only significant between FW_t and SW fish (Dunn's

244 test, $P = 0.0045$, Fig. 5B). No difference was observed between FW_i and FW_t.

245   2.2 Posterior kidney gene expression

246 No significant differences were measured in *ae1b* expression levels between SW and FW_t. However a

247 significantly lower expression was measured in FW_i compared to SW but not to FW_t (Dunn's test, $P = 0.0261$

248 and $P = 0.8787$, Fig. 4A).

249   No significant differences were measured in *ncc1* and *nkcc1a* expression levels between the three groups

250   (Kruskal-Wallis test, $P = 0.1016$ and $P = 0.2475$ respectively, Fig. 4B, C). Concerning *nkcc1b*, no differences

251   were measured between SW and FW_t (Dunn's test, $P = 0.5448$, Fig. 4D) but FW_i expression levels were

252   significantly lower than SW and almost significantly lower than FW_t (Dunn's test, $P = 0.0043$ and $P = 0.0529$

253   respectively). *nkcc2* expression was not significantly different between SW and FW_t or between FW_t and FW_i,

254   but it was significantly lower in FW_i than in SW (Dunn's test, $P = 0.2269$, $P = 0.8044$ and $P = 0.0096$

255   respectively, Fig. 4E). In FW_t, among *slc12a* cotransporters analysed, *ncc1* is the most expressed paralog in the

256   posterior kidney followed by the 5-fold less expressed *nkcc2* and the 25- and 50-fold less expressed *nkcc1a* and

257   *nkcc1b* (not shown).

258   Concerning *slc26a6* paralogs, *slc26a6a* exhibited a significant lower relative expression in FW_t compared to

259   SW (Dunn's test, $P = 0.0044$, Fig. 4F). In FW_i, *slc26a6a* expression was not significantly different from FW_t,

260   whereas for *slc26a6b* and *slc26a6c,* FW_t were at significant higher levels than FW_i (Dunn's test, $P = 0.0141$ and

261   Tukey's test, $P = 0.0018$, Fig. 4F, G, H) but not significantly different from SW. Overall, in FW_t the three

262   paralogs were similarly expressed (not shown).

263   *prlra* expression was significantly higher in FW_t than in SW (Tukey test, $P < 0.0001$, Fig. 5C) whereas *prlrb*

264   expression levels did not differ between SW and FW_t (Tukey test, $P = 0.8217$, Fig. 5D). A significantly lower

265   expression of both *prlr* paralogs (*prlra*, *prlrb*) was measured in FW_i compared to FW_t (Tukey test, $P = 0.0139$

266   and $P = 0.0472$ respectively, Fig. 5C, D).

267   **Discussion**

268   The comparative analysis of key genes and proteins involved in the maintenance of hydromineral balance in fish

269   exhibiting different capacities to tolerate FW is a powerful tool to investigate intraspecific variation in FW

270   tolerance in euryhaline species. In FW, fish have to minimise ion loss and compensate through active ion uptake

271   occurring at interfaces with their surroundings. Most studies investigating FW osmoregulation focused at the gill

272   level in adults or at integument level in larvae (mostly zebrafish), showing that FW tolerance relies on the

273   expression of key genes involved in hyper-osmoregulatory mechanisms (Evans and Clairborne, 2009). Less data

274   are available on the involvement and importance of the kidney in ion re-uptake. In this study, we highlight the

275   importance of taking into account not only the gill but also the posterior kidney in order to fully understand the

276   mechanisms of ion and acid-base regulation.

277   1.   Ion uptake capacities are not altered in gills of FW intolerant sea bass

278   Regarding gill ion uptake, slightly higher *nka α1a* expression levels and NKA protein activity were previously

279   measured in FW_i compared to FW_t in European sea bass (Nebel et al., 2005; L'Honoré et al., 2019). This could

280   indicate a compensatory response to the blood ion imbalance. In fact, several studies on *F. heteroclitus* or *D.*

281   *labrax* suggested that a higher Na^+/Cl^- ratio may indicate a more alkaline state (Scott, 2004; Scott et al., 2004a;

282   L'Honoré et al., 2019). In *D. labrax,* the FW_i phenotype was in this physiological condition (L'Honoré et al.,

283   2019) due to a high Na^+/Cl^- ratio. Regarding diverse transporters, we measured no difference in *ae1a* (*slc4a1a*)

284   relative expression between SW and FW phenotypes in gills but a higher variability in FW_i (Fig. 3A). AE1b has

285   been demonstrated as the dominant paralog in medaka gills and it was more expressed in FW media than in

286   saline waters from 10 to 30 ‰ (Liu et al., 2016). This seems not to be the case in European sea bass, as we

287   could only quantify *ae1a*, which was not differently expressed between salinities. In medaka gills, an opposite

288   response was measured regarding the two AE1 paralogs, AE1a and AE1b, when comparing SW and FW-

289   acclimated fish suggesting different functions according to the salinity. Using inhibitors and the scanning ion-

290   selective electrode technique (SIET), the role of AE1 seemed to be attributed to acid and Cl^- secretion in

291   seawater-acclimated medaka larvae (Liu et al., 2016). In European sea bass, the physiological role of AE1

292   paralogs still needs to be investigated. Moreover, a different expression pattern is observed between *ae1a* and

293   *vha-b*, which is not consistent with a functional link between apical VHA and basolateral AE1a as shown in

294   medaka. The slightly higher *ae1a* expression in FW_i compared to FW_t is therefore probably not linked to an

295   increased acid secretion by VHA. A 3-fold lower expression of *nkcc1a* was measured in FW compared to SW

296   acclimated fish gills (Fig. 3B), as it has previously been shown in this species (Lorin-Nebel et al. 2006;

297   Blondeau-Bidet et al., 2019) and many other teleosts (Hiroi et al., 2008; Inokuchi et al., 2008 Bollinger et al.,

298   2016). This is consistent with the role played by basolateral NKCC1 in ion secretion. According to Inokuchi et

299   al. (2017) and Blondeau-Bidet et al. (2019), FW transfer in Japanese and European sea bass might be followed

300   by a migration towards gill lamellae of seawater-type ionocytes differentiating into FW-type ionocytes (NHE3-

301   type cells) involved in Na^+ uptake. The observed decrease of *nkcc1a* expression in FW_i suggests a successful

302   functional shift from SW to FW-type ionocytes. *nhe3* seems also slightly more expressed in both FW

303   phenotypes compared to SW but unlike previous studies (Blondeau-Bidet et al., 2019), there is no significant

304   difference between salinities. Interestingly, the variability of expression levels for *nhe3* is higher in FW_i

305   compared to the other conditions, which could indicate differential responses within this group.

306

307 We measured a higher expression of *ncc-2a* in FW acclimated European sea bass than in SW (Fig. 3F) as it was

308 already demonstrated in this species (Blondeau-Bidet et al., 2019). This reinforces the hypothesis of the

309 differentiation of *ncc-2a* expressing ionocytes in FW, as it was observed in many other fish species such as

310 medaka and tilapia, exhibiting an higher relative expression of *ncc* (homologous to European sea bass *ncc-2a*) in

311 FW than in SW conditions (Hiroi et al., 2008; Inokuchi et al., 2008 Bollinger et al., 2016). FW_i fish also

312 increase slightly but not significantly their *ncc-2a* expression suggesting that at least some individuals

313 successfully differentiate NCC-type cells in gill filaments as shown previously in this species (Blondeau-Bidet

314 et al., 2019). Interestingly, expression levels of *ncc1* were slightly higher and extremely variable in FW_i

315 compared to the other groups (Fig. 3E), which was surprising as *ncc1* expression in the gills is generally low

316 (Inokuchi et al., 2017). A compensatory role of *ncc1* in Na^+, Cl^- uptake in intolerant fish gills could be

317 hypothesised as fish gills are known to have multiple ion uptake pathways, that compensate each other in case of

318 stressful and ion-poor environments (Hwang et al., 2011; Hwang and Lee, 2007).

319 *Slc26a6c* expression is significantly higher in SW and FW_i compared to FW_t (Fig. 3G). In SW, where fish do

320 not need to take up Cl^-, the high *slc26a6c* expression is surprising and might be linked to other functions as an

321 increased need to excrete HCO_3^-. In fact, studies dealing with *slc26a6c* in fish mostly focus on FW

322 environments and/or FW species (Bayaa et al., 2009; Perry et al., 2009). In this study we show that this gene

323 might also be of importance in SW conditions. The high expression in FW_i indicates that these fish may

324 compensate their low blood Cl^- levels through an increased Cl^- absorption and also activate the secretion of

325 HCO_3^- to restore blood pH levels (L'Honoré et al., 2019). In zebrafish, a higher expression level of *za6c* was

326 observed in the gills in hypo-osmotic conditions which is consistent with an involvement of this ion exchanger

327 in chloride uptake in apical membranes (Bayaa et al., 2009; Perry et al., 2009). By displaying enhanced

328 expression levels of Cl^- uptake genes such as *ncc1* and *slc26a6c,* FW_i sea bass seemed to activate Cl^- absorption

329 at the branchial level to compensate low Cl^- circulating levels measured previously (L'Honoré et al., 2019).

330   2. FW intolerant sea bass differentially regulate chloride reabsorption by the kidney

331 In FW_i posterior kidney, lower expression of *nka α1a* were previously measured compared to FW_t, associated

332 with lower Cl^- blood levels possibly due to a renal ion leakage (L'Honoré et al., 2019). In this study, we have

333 measured a lower expression of two other transporters involved in acid-base and hydromineral regulations (*ae1b*

334 and *slc26a6c*) in FW_i compared to FW_t suggesting that FW_i are actually less efficient to compensate ion loss at

335 the kidney level. Contrary to zebrafish in which *ae1a* is the predominant paralog of AE1 in the kidney, in *D.*

336   *labrax* only *ae1b* could be detected (Lee et al., 2011). Expression of *ae1b* was low in FW_i compared to the other

337   conditions. Its basolateral localisation has been demonstrated in goldfish (Fehsenfeld and Wood, 2018),

338   suggesting a role in acid-base regulation. FW_i may decrease the expression of this transporter in order to limit

339   excessive HCO_3^- levels in the blood as these fish already experience blood alkalosis (L'Honoré et al., 2019). In

340   *D. labrax* kidney, expression levels of *ncc1* (*slc12a3*) are higher than other *slc12a* cotransporters, which suggest

341   that NCC1 is predominant in *D. labrax* kidney for ion uptake. It is slightly more expressed in FW_t compared to

342   SW fish and is highly variable in FW_i. *ncc1* (*slc12a3*) has been demonstrated to be also highly expressed in FW

343   in Japanese sea bass kidney compared to SW (Inokuchi et al., 2017). In mefugu *Takifugu obscurus*, *ncc*

344   (homologous to European sea bass *ncc1*) is localised apically and highly expressed in collecting duct of FW-

345   acclimated fish, with a putative role in Na^+, Cl^- reabsorption (Kato et al., 2010). In killifish *F. heteroclitus*,

346   rainbow trout *Oncorhynchus mykiss* and torafugu *Takifugu rubripes*, NKCC2 was localised apically and a role

347   in Na^+, Cl^- reabsorption was suggested (Katoh et al., 2008; Kato et al., 2010). Compared to *ncc1*, *nkcc2* was

348   about 6.5 times less expressed in European sea bass kidney in FW_t and it rather seems downregulated in FW

349   media *vs* SW. Its role in ion uptake seems therefore secondary. FW_i sea bass exhibited the lowest expression

350   levels of *nkcc2* and are thus certainly not using this ion uptake pathway to compensate ion loss. The basolateral

351   *nkcc1a* and *nkcc1b* are respectively 15.8 and 27 times less expressed than *ncc1* in FW_t which is consistent with

352   the role of NKCC1 paralogs in ion excretion rather than ion absorption. Whereas *nkcc1a* expression did not

353   change between the different treatments and phenotypes, *nkcc1b* showed significantly lower expression in FW_i

354   compared to the other conditions. The physiological significance of this transcriptional down-regulation needs

355   to be further explored.

356   Among the three SLC26A6 paralogous genes investigated in the posterior kidney of European sea bass,

357   *slc26a6a* exhibited significant lower expression in FW_t compared to SW: *slc26a6b* and *slc26a6c* expressions

358   were not significantly modified between SW and FW_t, but they were lower in FW_i. A higher *slc26a6c*

359   expression in low-Cl^- FW compared to normal FW has already been demonstrated in zebrafish gills and kidney

360   with a suggested role in HCO_3^- excretion associated with a Cl^- (re)absorption (Bayaa et al., 2009). SLC26A6

361   family can exchange various anions with Cl^- such as sulfate (SO_4^{2-}), oxalate ($[COO^-]_2$) and bicarbonate (HCO_3^-)

362   (Mount and Romero, 2004). The role of SLC26A6a in SO_4^{2-}/Cl^- exchange in mefugu proximal tubules has been

363   already highlighted. According to Kato et al. (2009), SLC26A6a is acting as the main apical SO_4^{2-}/Cl^- exchanger

364   and its expression is enhanced under SW conditions. Our results are concordant with this study since both FW

365   sea bass phenotypes (FW_t and FW_i) exhibited lower *slc26a6a* expression levels than in SW. Less is known

366 about the role of SLC26A6b in the kidney. SLC26A6a and SLC26A6b have been shown to be both implicated

367 in HCO_3^- secretion by the intestine (Xie et al., 2002) but their role in SO_4^{2-} or/and HCO_3^- secretion needs to be

368 further investigated in the kidney of European sea bass and other teleost species.

369   3.   Prolactin receptor transcript levels differ according to FW tolerance capacities

370 Contrary to mammals where only one *prlr* gene exists, teleost can have two distinct paralogs due to genome

371 duplication events (Ocampo Daza and Larhammar, 2018). The relationship between PRLR and gene expression

372 patterns of osmoregulatory-related genes has not yet been described in European sea bass and needs more

373 attention. Gill *prlr* paralog expression levels seem to depend on circulating PRL levels as shown in Seale et al.

374 (2012) for *prlra* and on extracellular osmolality as shown for *prlrb* in Fiol et al. (2009). Pituitary PRL acts as

375 one of the major endocrine signals for FW acclimation in euryhaline teleosts (Manzon, 2002). Lower *prlra*

376 expression levels in SW compared to FW have been already shown in Mozambique tilapia (Breves et al., 2010;

377 Breves et al., 2011), whereas no differences where observed concerning branchial *prlrb* relative expression

378 between salinities. In our study, *prlr* paralogs expression patterns are not concordant with those described in

379 tilapia gills. Even if *prlra* seems to be slightly more expressed in FW_t than in SW, *prlrb* is significantly

380 overexpressed in SW compared to FW_t. We have previously shown that FW_i exhibited decreased blood

381 osmolality levels (L'Honoré et al., 2019), which could be one of the trigger to activate branchial *prlr* expression.

382 In fact, we measured slightly but not significantly higher mRNA levels of both *prlr* paralogs in FW_i compared

383 to FW_t. In zebrafish and Nile tilapia, PRL and PRLR positively regulate the expression of *ncc* in gill filament

384 cultures *in vitro* (Breves et al., 2013, 2014), which suggests that NCC-type cells might express PRLR. In our

385 study, we also highlighted higher branchial *ncc1* relative expression in FW_i compared to FW_t, suggesting a

386 similar regulation of *ncc1* expression levels by *prlr*. Moreover, slightly higher *nka α1a* expression levels and

387 increased gill NKA activity were previously measured in FW_i compared to FW_t (Nebel et al., 2005; L'Honoré et

388 al., 2019), potentially linked to an increased number of ionocytes to compensate low blood osmolality and low

389 circulating chloride levels.

390 In the posterior kidney, *prlra* is the predominantly expressed paralog (10-fold higher expressed than *prlrb*)

391 whereas in the gills, *prlrb* was 10-fold more expressed than *prlra*. No differences in *prlra* relative expression

392 have been reported following salinity change in Seale et al. (2012) but a lower relative expression of *prlrb* was

393 shown in FW compared to SW (Fiol et al., 2009; Breves et al., 2011). It seems different in European sea bass

394 posterior kidney where significantly higher expression levels of *prlra* are measured in FW_t compared to SW.

395   Moreover, no differences were observed for *prlrb* between SW and FW_t. Interestingly, both *prlra* and *prlrb*

396   were less expressed in FW_i compared to FW_t, highlighting that FW_i and FW_t do not exhibit the same regulation

397   mechanisms in response to the FW challenge. We showed a differential expression of prolactin receptors in FW

398   between FW_t and FW_i, with a higher, though not significant, over-expression of branchial prolactin receptors in

399   FW_i and a significantly lower expression of both renal prolactin receptors. These results suggest that FW

400   intolerance in European sea bass might be due to an altered PRL-associated endocrine response in FW_i.

401   **Conclusion**

402   This study is the first to highlight that freshwater intolerance in European sea bass is linked with lower mRNA

403   expression of *slc26a6* genes involved in Cl^- uptake in the posterior kidney. Regarding prolactin receptors, we

404   showed a differential endocrine control in FW between the tolerant and intolerant European sea bass associated

405   to the incapacity to maintain blood hydromineral balance in FW_i sea bass. Facing strong rainfalls during their

406   migration to transitional habitats like lagoons, European sea bass may undergo strong salinity decreases

407   triggering mortality in the freshwater intolerant phenotype. Thus, freshwater intolerance could affect some

408   European sea bass in their migrations by preventing them to access transitional environments. It remains to be

409   characterised how freshwater intolerance in *D. labrax* affects seasonal migratory behaviour in European sea

410   bass.

Fig. 1 Bayesian tree of *slc26a6*. A ML tree had identical topology for all nodes. Bootstrap values (in %) from the ML are shown before the Bayesian PP, confident nodes are indicated in red. Branch lengths represent the degree of divergence, with the scale bar indicating the distance representing 0.2 substitutions per position. The blue frame mainly comprises sequences of teleost *slc26a6c*. The green frame mainly comprises sequences of teleost *slc26a6a* and purple frame comprises sequences of teleost *slc26a6b*.
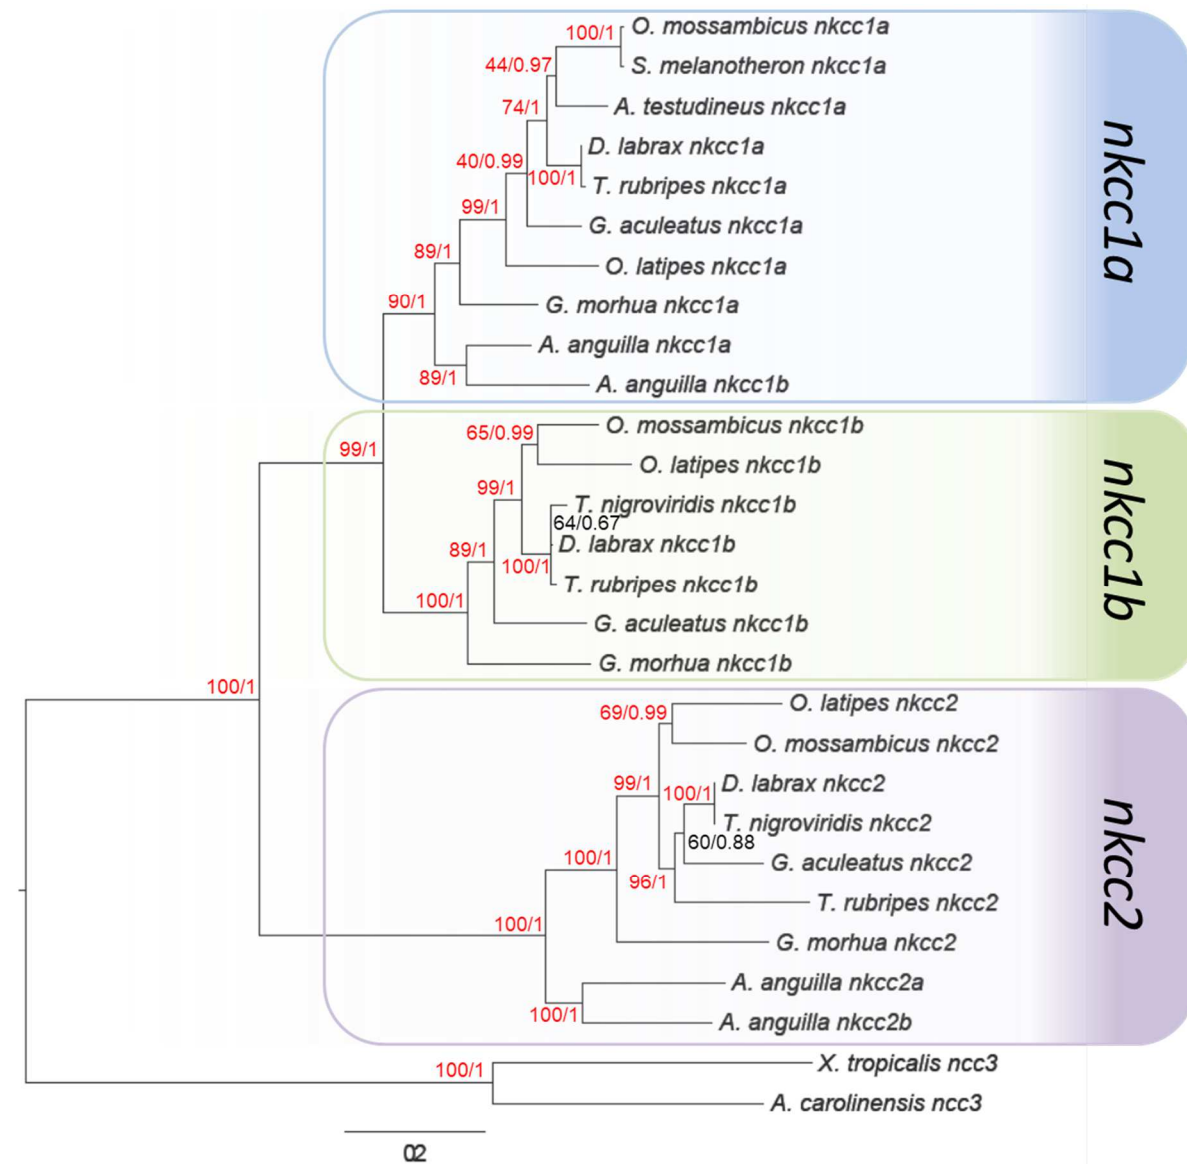

Fig. 2 Bayesian tree of *nkcc1a*, *nkcc1b* and *nkcc2* (*slc12a1a*, *slc12a1b* and *slc12a2*). A ML tree had identical topology for all nodes. Bootstrap values (in %) from the ML are shown before the Bayesian PP, confident nodes are indicated in red. Branch lengths represent the degree of divergence, with the scale bar indicating the distance representing 0.2 substitutions per position. The blue frame mainly comprises sequences of teleost *nkcc1a*. The green frame mainly comprises sequences of teleost *nkcc1b* and purple frame comprises sequences of teleost *nkcc2*.
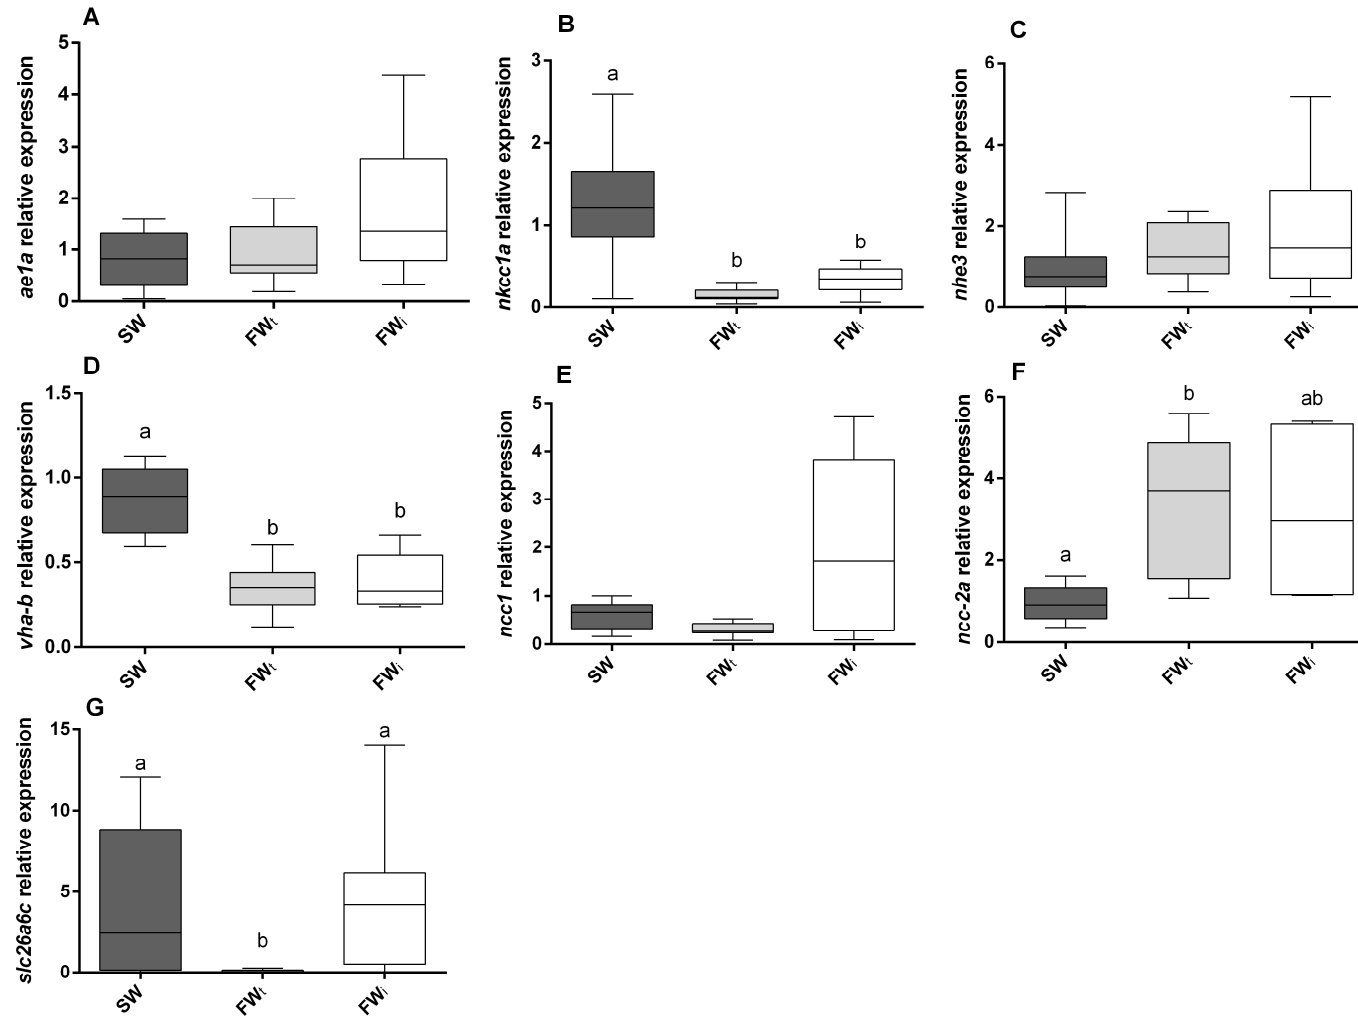

Fig. 3 Relative expression in gills of (A) *ae1a / slc4a1-1*, (B) *nkcc1a / slc12a2-1* , (C) *nhe3*, (D) *vha-b*, (E) *ncc1,* (F) *ncc-2a* and (G) *slc26a6c* in SW and after two weeks in FW. The expression has been normalised according to the expression of the elongation factor *ef1α*. Different letters denote significant differences between groups (one-way Anova followed by Tukey's test or Kruskal-Wallis followed by Dunn's test, $P < 0.05$, means ± s.e.m, N=6-16). SW: control fish in SW, FW_i: intolerant fish to FW, FW_t: tolerant fish to FW.
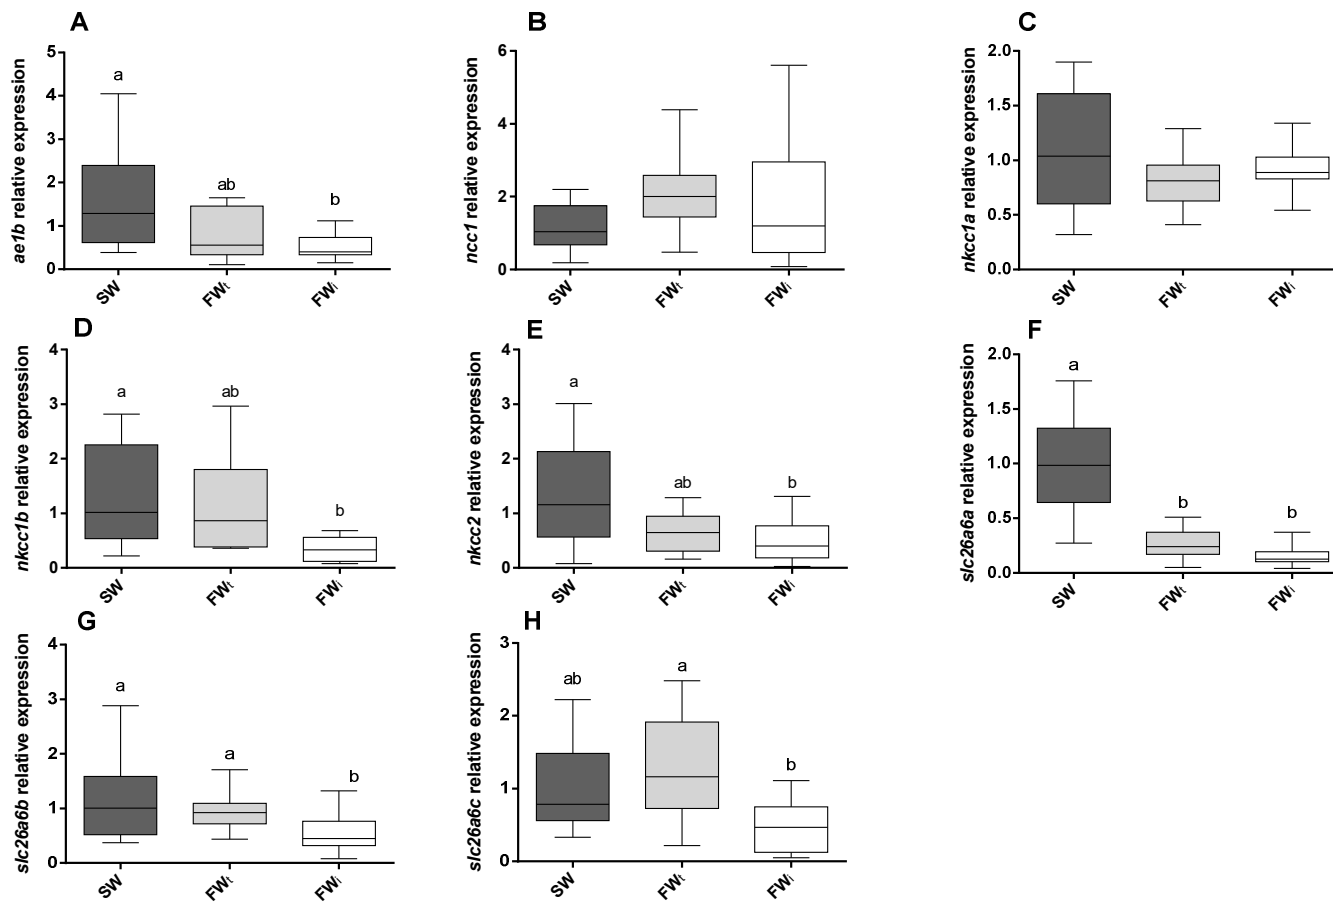

Fig. 4 Relative expression in posterior kidney of (A) *ae1 b / slc4a1-2*, (B) *ncc1 (slc12a3),* (C) *nkcc1a / slc12a2*, (D) *nkcc1b / slc12a2-like,* (E) *nkcc2 (slc12a1),* (F) *slc26a6a,* (G) *slc26a6b* and (H) *slc26a6c* in SW and after two weeks in FW. The expression has been normalised according to the expression of the elongation factor *ef1α*. Different letters denote significant differences between groups (one-way Anova followed by Tukey's test of Kruskal-Wallis followed by Dunn's test, *P* < 0.05, means ± s.e.m, N=6-16). SW: control fish in SW, FW_i: intolerant fish to FW, FW_t: tolerant fish to FW.
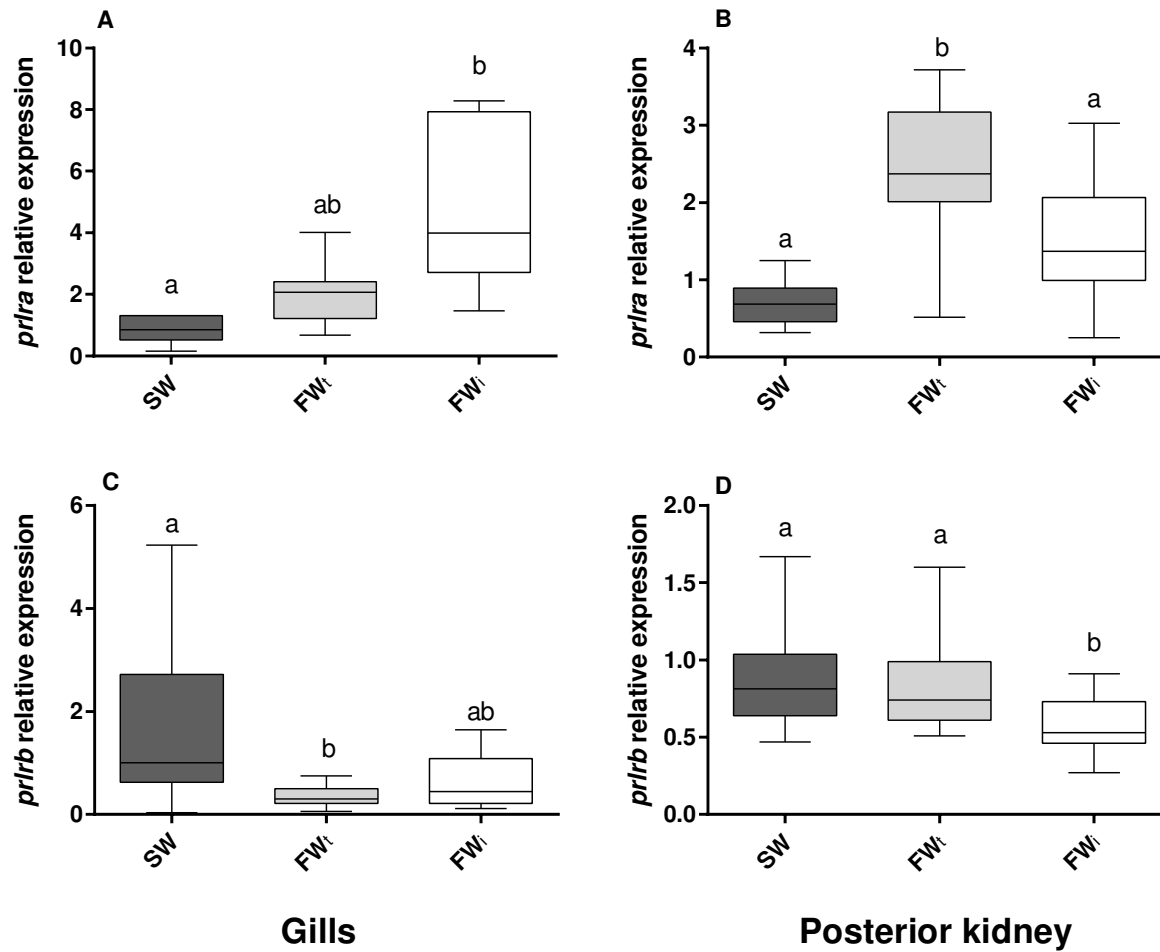

Fig. 5 Relative expression in the gills and in the posterior kidney of *prlr a* (A-C) and *prlr b* (B-D) in SW and after two weeks in FW. The expression has been normalised according to the expression of the elongation factor *ef1α*. Different letters denote significant differences between groups (one-way Anova followed by Tukey's test or Kruskal-Wallis test followed by Dunn's test, $P < 0.05$, means ± s.e.m, N=6-16). SW: control fish in SW, FW$_i$: intolerant fish to FW, FW$_t$: tolerant fish to FW.

Table 1 Primer sequences used for the gene expression analysis

Target gene	Primer name	Sequences ID	Sequence (from 5' to 3')	Efficiency	Reference
