Abstract

Cellulose nanocrystal (CNC) has recently gained much attention due to its unique properties such as abundancy, biodegradability, high strength, large surface area, functional ability, template structure, and sustainability. To broaden its application and enhance its compatibility with other materials, CNC can be modified via different methods. The modification is based on introducing new functions, including esterification, silylation, carbamation, polymerization, and so on. The application can concern many fields, such as polymer reinforcement, packaging, water treatment, textiles, biosensors, etc. Herein, we summarize the main approaches employed for the chemical modification and the use of the modified CNC material in the preparation of nanocomposite films and membranes, along with some emerging applications.

Keywords

Cellulose nanocrystal (CNC); self-assembly; chemical modification; membrane; film; nanocomposite.

45   **1.   Introduction**

46   According to the 2019 UN report, the world population is growing at an annual rate of 1.1%, which predicts a

47   global population of 8.5 billion in 2030, instead of the 7.7 billion recorded in mid-2019 (ONU, 2019). Admittedly,

48   the growth rate has been decreasing since 1950. However, it is still accompanied by strong demand for food and

49   increased exploitation of natural resources, which contribute to sizeable environmental stress and pollution

50   (Okada, 2002)(Sudhakar et al., 2018).

51   Thus, synthetic polymers are used extensively to meet humanity's needs and ensure a more convenient way of life.

52   These polymers often present many risks; they are persistent, hardly degradable, and their degradation by-products

53   are often toxic. Hence the use of degradable polymers, especially biodegradable ones, is encouraged.

54   Biodegradable polymers are defined as polymers that, in the presence of microorganisms in a natural environment,

55   degrade into carbon dioxide and water without generating toxic by-products (Okada, 2002).

56   Biodegradable polymers are classified into three main categories (1) polyesters produced by microorganisms, (2)

57   natural polysaccharides and other biopolymers, and (3) synthetic polymers, in particular aliphatic polyesters.

58   Polysaccharide materials get a growing interest due to their abundance, non-toxicity, and biodegradability, which

59   make them a good replacement for petroleum-based polymers(Garcia-Valdez et al., 2018); not only this, but they

60   present physicochemical properties that favor their use in several other fields (Fang et al., 2019a).

61   Cellulose belongs to this family of polysaccharides; it is the most abundant biopolymer on earth, with an annual

62   production estimated between 10^{11}-10^{12} tons (Nechyporchuk et al., 2016). It is used in several fields with the

63   following distribution: 28% in materials sciences, 17% in engineering, 16% in chemistry, 11% in chemical

64   engineering, 8% in physics and astronomy, 5% in biochemistry, genetics, and molecular biology, 4% in

65   environmental science, 3% in agriculture and biological sciences, 3% in medicine, 3% in energy, 1% in

66   immunology and microbiology and 1% in pharmacology, toxicology, and pharmaceuticals (Mohamed et al., 2017).

67   Cellulose can originate from wood, flax, cotton, and algae in the form of microfibrils. Mechanical and chemical

68   treatment of these microfibrils allows for obtaining cellulose nanofibrils (CNF) and cellulose nanocrystal (CNC)

69   (Hamad, 2002). Cellulose can also originate from bacteria and has a more crystalline structure than cellulose

70   extracted from plants.

71   This review is dedicated to cellulose nanocrystal (CNC) specifically. The first part concerns the origin, structure

72   of cellulose, and its ability to self-assemble and form films. The second part emphasizes the main chemical

73   modification of CNC surfaces applied during the last decade. In contrast, the last part gathers the techniques

74   applied to develop composite membrane and film based on CNC and their possible applications.

75   **2.   Cellulose origin, structure, and its property to form films**

76   Natural cellulose is originated from plants through the disintegration of the microfibers that form the cell wall

77   (Figure 1) (Mohamed et al., 2017) (Gopakumar et al., 2018) (Dong et al., 2021); extraction can be made by

78   chemical or mechanical treatment [14][13] and lead to two types of cellulose, cellulose nanofibrils (CNF) and

79   cellulose nanocrystals (CNC). This approach is known as top-down biosynthesis. CNF consists of two regions, an

80   ordered region, in other words, a crystalline region that confers high resistance to cellulose, and an amorphous

81   region which contributes to the flexibility of the material (Phanthong et al., 2018). CNF is characterized by a

82   diameter between 1-100 nm and a length between 500-2000 nm. When subjected to acid hydrolysis, cellulose

83   nanofibrils undergo transverse cleavage along amorphous regions because they have a lower density due to their

84   random orientation, resulting in the formation of cellulose nanocrystals (CNC) (Gopakumar et al., 2018)

85   (Mohamed et al., 2017). Their dimensions depend on the starting material, their diameter varies between 2-20 nm

86   (Sharma et al., 2020), and their length is between 100-500 nm (Gopakumar et al., 2018).
Figure 1. Illustration of the origin of natural cellulose (Han, 2019)**.**

Nanocellulose can also be obtained from bottom-up biosynthesis using bacteria (Bwatanglang et al., 2020). It is produced through the pores of bacteria membranes, so Gluconacetobacter is the species with the highest production ability (Belaustegui et al., 2020). There are other species such as Acinetobacter xylinumthrough (Sharma et al., 2020), Rhizobium, Agrobacterium, Sarcina and Alcaligenes (Belaustegui et al., 2020). Bacterial cellulose has the form of twisting ribbons with a diameter between 20-100 nm and length in micron order (Phanthong et al., 2018). It has the same structure as the cellulose extracted from the plant wall but presents higher purity and crystallinity (Revin et al., 2018).

The formula of cellulose is $(C_6H_{10}O_5)_n$, with n being the degree of polymerization that depends on the source of the cellulose and the method of isolation and purification [6]. It is composed of β-D-glucopyranose units linked together by β- (1,4) -glycosidic bonds (Arfin, 2020); each unit has 3 hydroxyl groups, a primary hydroxyl group on the C6, and two hydroxyl groups secondary on C2 and C3, presenting reactive sites that allow modification of cellulose (Fleet et al., 2008) (figure 2). The reactivity of these sites is governed by factors depending on the steric effects related to the supramolecular structure of cellulose and its isomerization. The C6 primary alcohol is ten times more reactive than the C2 and C3 secondary alcohols, thanks to the free rotation around the C5 and C6 bond. (Garcia-Valdez et al., 2018). These hydroxyl groups allow the formation of inter and intramolecular hydrogen bonds (Chu et al., 2020)(Kausar, 2020). These bonds allow the formation of a solid network giving cellulose a fibrillated structure, high resistance, and insolubility in water and most organic solvents (Phanthong et al., 2018).
106
107 **Figure 2. Cellobiose unit composed of two β-D-glucopyranose units.**

108 CNC suspension behaves as a cholesteric crystalline liquid; this phase can be preserved after evaporation of the

109 solvent, which leads to a well-structured iridescent film (Frka-Petesic et al., 2017). Factors such as the technic of

110 extraction and concentration of the suspension have a direct impact on the self-assembly. CNC extracted using

111 sulfuric acid exhibits a stable suspension due to sulfate groups negatively charged attached to the surface (Tran et

112 al., 2020); this stability is a prerequisite to having self-assembly for cases where CNC is isolated by using

113 phosphoric acid or hydrochloric acid, CNC will not be enough charged and will tend to flocculate which impacts

114 the self-assembly negatively (Parker et al., 2018).

115 Above a particular concentration, CNC whiskers aggregate to form tactoids. While drying, they stack into layers.

116 Each layer has a direction orthogonal to the nematic axis, and the layers are modulated to a helicoidal form

117 (Dumanli et al., 2014) (Frka-Petesic et al., 2017), as shown in figure 3. The origin of the helicoidal arrangement

118 is the chirality of CNC obtained due to D-glucose units (Tran et al., 2020). This specific structure displays CNC

119 film with optical functionalities that favor its use in biophotonic material (Xiong et al., 2019).

120 Besides the optical properties, films based on nanocellulose show good mechanical properties compared to films

121 made from other materials (tensile strength of 100–300 MPa and a modulus of 5–30 GPa) (Fang et al., 2019b).

122 Thanks to their high surface area, they can be used as templates with other materials such as TiO_2, carbon, and

123 organosilica (Lagerwall et al., 2014). Therefore, integrating novel functionalities in the CNC structure can extend

124 their application as films in many different fields.

3. Chemical modification of cellulose nanocrystal

Cellulose can be chemically modified via its hydroxyl groups, mainly the primary alcohol group. This modification can broaden its application and improve its compatibility with other materials. Modification could be done following different strategies depending on the species inserted.

3.1. Graft polymerization

Graft polymerization is considered a good approach to modifying the surface and endowing it with new physical and chemical properties (Wohlhauser et al., 2018). It consists of attaching a sequence of monomers to the cellulose backbone. The inserted polymer will give new properties to cellulose depending on its functional group (Roy et al., 2009). Two main approaches are used for graft polymerization, the "grafting to" and the "grafting from" approach (figure 4). The "grafting to" approach involves attaching a pre-formed polymer to the cellulose's functional site via the polymer's reactive end group (Oberlintner et al., 2021). This approach can be limited because of the steric hindrance; larger polymer chains can intertwine and prevent the functional group from reaching the cellulose surface (Kedzior et al., 2019). While the "grafting from "consists of the immobilization of the initiator on the cellulose surface to allow the polymer chain's growth. This approach is widely used because it provides a high grafting density with a good control length (Wohlhauser et al., 2018) (Kedzior et al., 2019). The two approaches can be applied by using different techniques such as atom transfer radical polymerization (ATRP), reversible addition-fragmentation chain transfer (RAFT), nitroxide-mediated radical polymerization (NMP), ring-opening polymerization (ROP), and free radical polymerization.
Figure 4. Schematic representation of (a) grafting to the CNC surface and (b) grafting from where polymerization is initiated from the CNC surface. (Kedzior et al., 2019). Elsevier Copyright (2019).

3.1.1. Atom transfer radical polymerization (ATRP)

As its name implies, ATRP relies on the transfer of halogen atoms between a dormant species (R-X) and a transition metal catalyst M_t^n-X/ligand (Mishra & Kumar, 2012). The active radical is generated due to the transfer of the halogen atoms from the dormant species to a transition metal complex by oxidative addition. The radical created will then react with the monomer to further form a polymer chain (Roy et al., 2009).
Figure 5. Modification of cellulose by grafting polymer via ATRP polymerization (Roy et al., 2009) The Royal Society of Chemistry, Copyright (2009).

ATRP has been largely used to graft polymers to substrates due to its ability to form a well-controlled polymer chain with a high grafting density. A large panel of monomers was attached to cellulose nanocrystals, as summarized in table 1. The main way used to start the surface-initiated ATRP (SI-ATRP) is to first graft the initiator to the surface of CNC by esterification; the initiator usually applied are 2-Bromoisobutyryl bromide "BIBB" and α-Bromoisobutyric acid "BIBA", then the polymer chain grows from the surface. The main negative point of using ATRP is the use of toxic transition metal complexes and the need to separate them from the final product. So, to overcome these drawbacks and decrease the amount of metal, Sèbe et al. used Activator Re-Generated by Electron Transfer ATRP (ARGET-ATRP) to graft polystyrene and poly(4-vinyl pyridine). This

167 approach uses a reducing agent in excess to regenerate the catalyst regularly from the deactivated form. By

168 comparing ATRP and ARGET-ATRP, it has been observed that ARGET promotes the formation of a longer chain

169 with a low grafting density; this is because the propagation step is fast, and the amount of the catalyst is of the

170 order of ppm (Z. Zhang et al., 2019). Another approach was applied by Cunningham et al. to reduce the amount

171 of catalyst, based on the use of Cu(0) as a reducing agent. The Cu(0) was added in the form of wire and was easily

172 removed at the end. (Arredondo et al., 2017)

173
174 **3.1.2.   Reversible addition-fragmentation chain-transfer (RAFT)**

175 RAFT is an effective process for controlling living radical polymerization; it enables the synthesis of

176 macromolecular with complex architecture (Semsarilar & Perrier, 2010). It involves thiocarbonylthio compounds

177 that serve as chain transfer agents. The effectiveness of this agent relies on the radical leaving group "R", the

178 activating group "Z" and its compatibility with monomers (Moad et al., 2013). Table 2 regroups polymers with the

179 corresponding RAFT agent used. The R group needs to be a good homolytic leaving group and be able to reinitiate

180 new polymer chains. In contrast, the Z group must provide the RAFT agent with good resonance stabilization and

181 polar effects to be more active (Tsang & Holdcroft, 2012). Grafting polymers to CNC by RAFT polymerization

182 surface can be applied by immobilizing the RAFT agent to the surface via either the Z approach or the R approach.

183 In the Z approach, the di(tri)thio group is permanently grafted to the cellulose surface while the chain grows aside.

184 In the R approach, the polymer chain grows from the surface (Boujemaoui et al., 2016). Li et al. used another

185 method to graft "PDMAEMA-*b*-PGMA-*b*-PHFBA "to the CNC surface. The polymer was first synthesized by

186 RAFT, and then it was grafted onto cellulose via the reaction between the epoxy ring of PGMA and the hydroxyl

187 group of the cellulose. The hydrophobicity increased, confirming successful grafting (J. Zhou et al., 2021).

188 **3.1.3.   Ring-opening polymerization (ROP)**

189 ROP is a polymerization technique that involves monomers such as epoxides, cyclic esters (ex. lactones, lactides),

190 and cyclic carbonates (Sarazin & Carpentier, 2015). ROP occurs following mechanisms such as radical, cationic,

191 anionic, and ring-opening metathesis polymerization (Nuyken & Pask, 2013). It mainly depends on the monomer,

192 catalytic system, and the initiator used (Carlmark et al., 2012). The hydroxyl group can be used as an initiator for

193 ROP. Thus modification of cellulose using ROP seems interesting (Carlsson et al., 2015) since no prior chemical

194 treatment will be needed (Carlmark et al., 2012). Grafting PLA from CNC surface was extensively studied using

195 Tin (II) octoate as a catalyzer (Table 3); this grafting aims to enhance CNC's ability to adhesion with another

196 polymer matrix to improve its properties.

Table 3. Summary of polymers grafted to CNC via ROP.

3.1.4. Nitroxide-mediated polymerization (NMP)

NMP is based on the use of nitroxide to initiate the polymerization without the implication of another radical source or the need for a metal catalyst. The main characteristic of the alkoxyamine that could be used for NMP is its ability to provide reactive radical to initiate polymerization and form a stable mediating nitroxide radical. NMP can be used to graft polymer on a natural surface such as cellulose. For the" grafting from" approach, CNC can be functionalized with nitroxide forming, thus an alkoxyamine able to induce polymerization. Roeder and co-workers first graft BlocBuilder® (BB) on CNC via a covalent bond to the vinyl group of 4-chloromethyl styrene (CMS) that was already inserted into CNC. The polymerization was generated after adding the monomer (Roeder et al., 2016). The "Grafting to" approach was applied by Glasing et al., where they first modified CNC with glycidyl methacrylate (GMA). The polymerization was generated in the presence of macroalkoxyamines based on N-hydroxysuccinimidyl BlocBuilder® and polymers such as Styrene, N, N-(diethylamino)ethyl methacrylate(DEAEMA), and N-3-(dimethylamino)ethyl methacrylamide (DMAPMAm) (Glasing et al., 2017).

3.1.5. Free-radical polymerization (FRP)

FRP is an uncontrolled polymerization technique, and the synthesized polymers usually have a high dispersity. Several methods initiate FRP, such as chemical, thermal, and radiation. Jeun and co-workers successfully grafted 1H,1H,2H,2H-perfluorodecyl acrylate (PFDA) using electron beam (e-beam) irradiation as a technique to initiate the polymerization. The advantage of e-beam is that it avoids the application of harmful compounds (Jeun et al., 2019). Plasma was also applicated to graft polymers on CNC surfaces. Here, we can cite the research done by Alanis et al. where they graft different monomers (caprolactone, styrene, α-farnesene) (Alanis et al., 2019). The main advantage of this technique is the possibility of polymerizing a wide range of monomers.

3.2. Grafting small molecule

Grafting small molecules on the CNC surface is advantageous. Diverse functions can be grafted using reactions with suitable conditions and high yield. Many strategies are applied; we discussed below click chemistry, sylilation and esterification.

3.2.1. Click chemistry

Click chemistry was first introduced by Sharpless et al. in 2001, describing reactions that satisfy the following criteria: stereospecific, giving high yields, modular, wide in scope, implies simple experimental conditions, the product should be easily isolated and involve only benign solvent if it is necessary (Kolb et al., 2001). The commonly used click chemistry reactions are Diels-Alder, thiol-ene, the azide-alkyne Huisgen, and the Cu^1-catalyzed azide-alkyne cycloadditions (Filpponen, 2014). Click chemistry was used to modify CNC by either

239 bringing two CNC chains together (Filpponen, 2014) or grafting new functionalities to its surface. CNC can be

240 functionalized with an Azide or an alkyne functional group for the Azide-alkyne cycloaddition, and Thiol-ene

241 click chemistry CNC should be modified with thiol function or a methacrylate (Table 4).

Modified CNC	Inserted species	Click-reaction	Ref
CNC-Azide	CNC-alkyne	Cu(I)-catalyzed Huisgen 1,3-dipolar	(Filpponen, 2014)
CNC-Azide	Propargyl-terminated poly(ethyl ethylene phosphate) (propargyl-PEEP)	Cu(I)-catalyzed azide-alkyne cycloaddition (CuAAC)	(H. Wang et al., 2015)
CNC-Azide	Polycaprolactone diol-C≡CH	(CuAAC)	(L. Zhou et al., 2018)
Fe$_3$O$_4$/CNC-Azide	Propargyl alcohol	(CuAAC)	(Movagharnegad et al., 2018)
CNC-methacrylate	1H,1H,2H,2H-perfluorodecanethiol	Thiol-ene	(Aalbers et al., 2019)
CNC-SH	N-phenyl maleimide	Thiol-ene	(J. L. Huang et al., 2014)
CNC-alkyne	Azide-polycaprolactone diol	(CuAAC)	(L. Zhou et al., 2019)

242 **Table 4. Summary of species grafted to CNC via Click reactions**

243 **3.2.2. Silylation**
244
245 CNC can be modified by inserting a Siloxane group to enhance the hydrophobicity of cellulose (Anpilova et al.,

246 2020) and increase the thermal stability of the modified CNC (Khanjanzadeh et al., 2018). Zanata et al. developed

247 crosslinked aerogels based on cellulose nanocrystals using 3-isocyanotopropyltriethoxysilane (IPTS), the

248 developed material exhibit an amphiphilic character (De Morais Zanata et al., 2018). Silylation of CNC can have

249 another purpose: endowing nanocellulose with flame retardancy. In this sense, Kim and co-workers modified CNC

250 with Tris(2-chloroethyl) phosphate (TCEP) to incorporate it into a polyurethane matrix, and the result showed an

251 increase in the limiting oxygen index up to 28% (Kim et al., 2020). To enhance CNC adsorption capacity toward

252 CO_2, Zhu et al. modified it with 3-(2-aminoethylamino)-propyl methyl dimethoxy silane (APS); the results

253 revealed that even after ten cycles of adsorption and desorption the adsorption capacity remained above 85% which

254 emphasize the APS-CNC aerogel potential to adsorb CO_2 (W. Zhu et al., 2020). Incorporating organosilane-

255 modified cellulose nanocrystal into natural rubber matrix proves its efficiency in improving mechanical properties

256 of the latter; as Singh and co-workers showed in their research (Singh et al., 2020).

257 **3.2.3. Esterification**
258
259 The modification of cellulose nanocrystals by esterification is an interesting method to modify CNC, as

260 summarized in table 5. Esterification can be applied using a variety of catalysts such as sulphuric acid, hydrochloric

261 acid, iodine, potassium carbonate, and triethylamine, to name a few (Ávila Ramírez et al., 2017). The degree of

substitution (DS), defined as the average number of substituent groups graft per base unit (anhydroglucose unit) for cellulose the DS may range from zero to three since it has three reactive hydroxyls (Wiley & Sons, 2011), depending on the concentration of the reagents, the concentration of catalyst and the removal of water (Abraham et al., 2016).

Grafted species	Degree of substitution	Usage	References
Canola oil fatty acid methyl ester	0.5	Hydrophobic coating agent	(Wei et al., 2017)
Acetic anhydride	2.18	Reinforcing nanocomposite	(Abraham et al., 2016)
Lauroyl chloride	0.2-2.4	Reinforcing nanocomposite	(Trinh & Mekonnen, 2018)
Succinic anhydride	1.6-2.2	Dye removal	(Emam & Shaheen, 2019)
Acetic anhydride	0.18-0.34	Reinforcing nanocomposite	(Ávila Ramírez et al., 2017)
Vinyl acetate- Vinyl cinnamate	-	Emulsifying agents	(Seìbe et al., 2013)
Palmitoyl chloride	0.3-0.8	Improve dispersibility	(Fumagalli et al., 2013)
Long-chain aliphatic acid chlorides	-	Reinforcing nanocomposite	(Bendahou et al., 2015)
Phenylacetic acid	0.5	Composite manufacturing	(Espino-Pérez et al., 2014)

4. Nanocomposite film and membrane-based on cellulose nanocrystal

**4.1. Preparation of cellulose nanocrystal composite film and membrane**

Cellulose nanocrystals can be used as templates with the ability to form mesoporous films (Y. Huang et al., 2020). The significant problems CNC films face are their brittleness and poor water resistance that prevent their applications. Huang et al. developed a flexible composite film using poly (ethylene glycol) diacrylate (PEGDA) to overcome this issue. PEGDA encapsulates CNC by forming a three-dimensional crosslinking network.

PEGDA was mixed with a photoinitiator, then added to a CNC suspension and cast in a plastic Petri dish. The film was obtained by evaporation-induced self-assembly (**EISA**); by the end of this step, CNC and PEGDA interacts via hydrogen bonding. To stimulate the encapsulation of PEGDA to CNC, the film was exposed to UV. It was observed that the tensile strength decreased with the increasing amount of PEGDA, while the flexibility of the composite film has been improved compared to the pristine CNC film. After soaking the prepared film for 24 h, its structure was preserved, which shows its good water-resistant property. The three-dimensional structure of the developed film allows its applications as a water-content detector, anti-counterfeiting label, and photonic paper (Y. Huang et al., 2020).

To avoid the coffee-ring phenomenon obtained due to the heterogeneity structure while the drying process, Zhang et al. used vacuum-assisted self-assembly (**VASA**) to help obtain a well-oriented and structurally homogeneous CNC film. CNC suspension was filtered using poly(tetrafluoroethene) (PTFE) as a support membrane under

287 vacuum. After filtration and completely drying, CNC film was peeled off from PTFE. The effect of prior sonication

288 and the volume of suspension was evaluated to emphasize their impact on the iridescent of the obtained film. It

289 was reported that the sonication duration does not impact CNC crystallinity, but it is responsible for the coloration

290 variation of the films obtained. A long sonication time is needed to obtain an iridescent CNC film via VASA. Beck

291 et al. reported that sonication leads to the rejection of ions from the bound-water layer, which leads to a large pitch

292 because of the weak chiral interaction between CNC particles (Beck et al., 2011). The amount of CNC also

293 impacted the chiral nematic structure of the film. While changing the suspension volume, films with different

294 colors were obtained, suggesting that the chiral nematic structure's helical pitch varies with the CNC film's

295 thickness. The formation kinetics of CNC film also impact the iridescent of the latter so that variating the vacuum

296 degree induces a color change (Q. Chen et al., 2014).

297 Vacuum filtration was used by Sulaiman et al. to prepare a nanocomposite film using a **layer-by-layer** approach.

298 The group developed a bi-layer electrode using as layers polypyrrole/ graphene oxide (GO) and polypyrrole/CNC.

299 The bilayer was prepared by first deposing PPy/ GO layer on a membrane filter via vacuum filtering and then

300 adding the second layer PPy/CNC by applying vacuum filtration. After each deposition, the layers were washed

301 with deionized water (Kulandaivalu & Sulaiman, 2020). Wagberg et al. reported that skipping the rinsing step will

302 gender a rougher and less-defined layer (Wågberg & Erlandsson, 2021). After drying, the free-standing film was

303 peeled off from the membrane. Multilayer film can be assembled via electrostatic interaction, hydrogen bonding,

304 hydrophobic, and covalent bonding (Kulandaivalu & Yusran, 2019). Herein the interaction between the two layers

305 was insured by hydrogen bonding between the oxygen in GO and the hydroxyl group of CNC. The assembly of

306 the two layers PPy/GO|PPy/CNC induced active sites, which attributed to the generated film's high surface area

307 (Kulandaivalu & Sulaiman, 2020). In the same context, Xia et al. developed a tri-layer membrane using mid-layer

308 polydimethylsiloxane (PDMS), surrounded by two layers of nanocrystals cellulose modified with

309 methyltrimethoxysilane. The silylation was intended to render the CNC surface hydrophobic and increase its

310 dispersion in PDMS. The modification did not impact the crystallinity of CNC, which endowed the PDMS matrix

311 with rigidity, one of the fundamental properties of CNC that favored its use as a reinforcing agent. The three layers

312 were covalently bonded due to the crosslinking curing reaction applied during the preparation of the layers that

313 provide strong adhesion between the layers. Barrier performance of the multilayer membrane improved compared

314 with neat PDMS material; it was noted that oxygen permeability decreased due to the presence of Si-CNC, which

315 was explained by the fact that Si-CNC nanoparticles block O_2 from diffusing while crossing the composite layers

316 (Xia et al., 2018).

317 Shojaeiarani et al. developed a nanocomposite film based on poly (lactic acid) and CNC using EISA and **spin**

318 **coating**. A mixture of PLA-CNC was prepared in chloroform, injected into a spin coater plate, and kept for 180s

319 under a constant spin speed of 150 rpm; the film was obtained after the evaporation of solvent at room temperature

320 (figure 7). It was concluded that spin coating allows good dispersion of CNC due to the high drying rate, compared

321 to EISA, which improves the degree of crystallinity and decreases the hydrophilicity (Shojaeiarani et al., 2020).
322
323 **Figure 7. Formation of the film via the spin-coating method** (Shojaeiarani et al., 2020)**.** Elsevier Copyright
324 (2019).

325 **Electrospun** nanocomposite mats-based chitosan/Polyethyleneoxide /CNC was prepared by Nasri et al. using

326 CNC isolated by hydrochloric acid or sulphuric acid to investigate the effect of surface functionalities of CNC.

327 During the electrospinning process, it was observed that the jet was stable for the solution prepared with CNC

328 (HCl), which led to the formation of fibers of good quality. In contrast, the fiber obtained by using CNC (H_2SO_4)

329 was non-uniform. The mechanical properties increased with the reinforcement of the matrix fiber with both types

330 of cellulose nanocrystals (Naseri et al., 2015). In another study by Nair et al., they reported a decrease in both

331 tensile strength and Young's modulus for nanocomposite fiber mats based on CNC and Cellulose acetate (CA),

332 and it was explained by the fact that CNC acted more defects due to the aggregation during the loading (Naseri et

333 al., 2015).

334 **4.2. Application of cellulose nanocrystal composite membrane and film**

335 Film and membrane have promising use in electronics, sensors, solar cells, water treatment, and so on. Several

336 studies have been carried out in this direction. They have shown the possibility of integrating cellulose into

337 different matrices to develop films with good performance depending on their field of application.

338 **4.2.1. Conductive materials**

339 To endow cellulose with electrical properties, a conductive material such as conductive polymers (Polyaniline,

340 Polypyrrole, etc.), metallic particles, and conductive carbon material was combined with cellulose, so the

341 developed nanocomposite material exhibits properties of both materials (Du et al., 2017). Polyaniline (PANI), one

342 of the conductive polymers, has drawn much attention due to its high electrical conductivity. However, PANI

343 tends to aggregate, limiting its application (S. Wang et al., 2016)(Nepomuceno et al., 2021). PANI was synthesized

in the presence of other materials such as CNC to overcome this issue. Nepomuceno et al. synthesized PANI via in situ polymerization in the presence of CNC; the latter played the role of a backbone to PANI deposition. The group reported that while adding aniline to CNC, the amino group of aniline interacted with the hydrogen bond between the hydroxide group of CNC, which promoted the in-situ polymerization. The negative charge on the CNC surface interacted with positively charged amine groups of polyanilines which slowed the polymerization time. In other words, increasing the amount of aniline monomer enhanced the probability of polymerization occurring, thus decreasing the polymerization time. Increasing PANI concentration led to CNC coating, facilitating electrons' mobility. For a PANI/CNC ratio of 0.4, the conductivity obtained was 8.9×10^{-1} S cm^{-1}; this value matches the requirement for using sensors and electromagnetic interference shielding (Nepomuceno et al., 2021). To increase the stability of CNC/PANI, Wang et al. used cellulose nanofibers as a dispersant. The obtained film exhibits a conductivity of 104.7 S cm^{-1}. The group reported that the presence of CNF avoids the agglomeration of CNC and PANI (S. Wang et al., 2016). Wu et al. have also used polypyrrole with CNC to develop a nanocomposite material for supercapacitor application. To obtain a well-controlled and uniform coating of PPy, poly(N-vinyl-pyrrolidone) PVP was first adsorbed on the CNC surface to modify the hydrophilicity of CNC and favored the coating of PPy. PPy also acts as a stabilizer that inhibits the formation of aggregates. Due to hydrogen bonds between the carbonyl groups of PVP and the N-H group of pyrroles, the PPY growth uniformly on PVP-coated CNC. The core-shell PPy/PVP/CNC material exhibit a conductivity of 36.9 S cm^{-1} (X. Wu et al., 2014). Incorporating nanoparticles into CNC matrices enhances conductivity, as reported by El-Nahrawy et al. The group developed a nanocomposite material consisting of CNC coated with PPy and Ag Nanoparticles and (Ni_2O_3) nanoparticles. The formed material had unique electroconductive properties due to the support of PPy with the presence of an excess of charge carries (El-nahrawy et al., 2020).

4.2.2. Water treatment

Nanocomposite membranes are promising materials for mitigating fouling and compromise between selectivity and permeability. Cellulose nanocrystal presents an excellent material to be part of this nanocomposite membrane, so the last can exhibit all the properties mentioned. The choice of cellulose nanocrystal is because they can be easily functionalized with other moieties to enhance their efficiency in retaining pollutants. Moreover, their hydrophilic nature due to the presence of hydrophilic groups can help mitigate fouling (C. Xu et al., 2020). The presence of CNC contributes to the membrane's good mechanical properties by increasing the tensile strength (Cruz-Tato et al., 2017), and it is favored over other nanoparticles because it is considered a renewable, non-toxic,

373   and biodegradable material (Asempour et al., 2018) solving thereby leaching problem related to toxic

374   nanoparticles.

Composite material	%CNC	Pollutants	Removal rate	Reference
PES	2 % (wt%)	Humic acids (HAs) Bovine serum albumin (BSA)	71.9% (HA) 82.7% (BSA)	(Langming Bai et al., 2020)

PES	-	Aqueous crude oil emulsion	-	(M. B. Wu et al., 2019)
PA	-	Na_2SO_4	96.7%	(J. J. Wang et al., 2017)
GO/PA	-	Na_2SO_4	94.2%–97.2%	(C. Y. Zhu et al., 2021)

375   **Table 6.Summary of composite membranes based on CNC for water treatment with the targeted**
376   **pollutants and the removal rate**

377   CNC was incorporated with different materials such as polyethersulfone (PES), polyamide as an active layer (PA),

378   polysulfone (PSF), and polyvinylidene fluoride (PVDF), among others to remove diverse pollutants (Table 6).

379   Several researchers used PES to develop nanocomposite membranes due to its high thermal stability and chemical

380   resistance in organic solvents (Langming Bai et al., 2020). Janoobi et al. developed a nanocomposite membrane

381   based on PES and CNC to remove color and reduce chemical oxygen demand from industrial wastewater. The

382   group first modified CNC with (3-aminopropyl) triethoxysilane (APTES), then mixed it with polyethersulfone

383   polymer. The membrane was then prepared based on this blend solution. Adsorption tests showed that the presence

384   of CNC enhanced the removal of color and contributed to the reduction of chemical oxygen demand. The

385   adsorption was ensured by hydrogen interaction between hydroxyl groups of CNC and the different groups of the

386   colored compounds. The presence of amino group from APTES help increase the removal of color due to its

387   interaction with anionic groups of color, so they play the role of new adsorption sites (Jonoobi et al., 2019). Another

388   reason to prepare composite membranes using CNC is to prevent fouling. Bai et al. used CNC due to its hydrophilic

389   property. Comparing composite membrane based on CNC and PES to neat PES membrane, they note that the

390   composite membrane is more hydrophilic, has a higher porosity than the neat one, and exhibits good performance

391   in terms of antifouling ability. However, the excess of CNC renders the membrane surface rough due to the poor

392   dispersibility of high concentrated solution of CNC, which impact the porosity and the permeability of the

393   nanocomposite membrane too (Langming Bai et al., 2020). To endow a nanofiltration membrane with antifouling

394   and antibacterial properties, Xu et al. prepared a composite membrane by incorporating CNC and Ag nanoparticles

395   into an active polyamide layer, and PES was applied as the support material for this active layer. The developed

396   membrane exhibits good antifouling and antibacterial performance and helps reduce energy consumption known

397   for the nanofiltration process due to the enhancement in water flux and salt rejection (C. Xu et al., 2020). In the

398   study by Jackson et al., CNC was used only as an anti-microbial agent and incorporated into the membrane; the

399   result showed the inactivation of up to 89% of *Escherichia Coli*. The group relates the anti-microbial activity of

400   CNC to its rod-like morphology that damage the cell membrane of the bacteria after contact (figure 8) (Jackson et

401   al., 2021).

402
Figure 8. Representative scheme of membrane-based on CNC with antibacterial activity (Jackson et al., 2021)**.** American Chemical Society Copyright (2021).

4.2.3. Packaging

CNC has been widely used in packaging as a reinforcing material. Due to the CNC network, the mechanical properties of the reinforced material improve significantly (S. Liu et al., 2019). Furthermore, this network plays the role of a barrier to water vapor and oxygen, one of the crucial criteria for selecting the packaging material. Packaging films based on CNC blending with PLA and PVA were extensively studied and showed promising results in thermal stability, stiffness, and anti-microbial activity. (Pal et al., 2019) reinforced PLA with CNC and reduced graphene oxide (rGO). The developed film exhibited a higher crystallinity due to the strong physical interaction between CNC and PLA. Thus, the crystallinity increase reduces the water vapor permeability value. (Salmieri et al., 2014) developed a bioactive packaging film based on CNC-PLA coated by nisin, the results showed a promising inhibiting capacity against *Listeria monocytogenes*. On the other hand, (Dey et al., 2021) emphasize the antifungal property of CNC, incorporated into PVA film, against postharvest pathogens. The study showed the potential application of CNC for the packaging of fresh fruits. CNC was incorporated into other natural polysaccharides, such as alginate, chitosan, and carrageenan (Yadav et al., 2019). In general, polysaccharides are a promising material for packaging due to the considerable advantages they present as the preservation of aromas, inhibition of oxygen penetration, and water absorption, not to mention their abundance and price (Hui Li et al., 2020).

4.2.4. Biomedical

422   CNC has been known to be biocompatible and non-toxic for biomedical applications. It can be used for artificial

423   blood vessels, tissue engineering (Dugan et al., 2010), drug delivery(Lin et al., 2016), etc. (Zeimaran et al., 2019)

424   reinforced urethane with CNC to develop a self-healing nanocomposite film. The developed material showed an

425   excellent cytocompatibility toward human dermal fibroblasts, making it promising for application in material

426   engineering. In a more concrete study, (L. Qin et al., 2020) introduced CNC into a collagen-based film for corneal

427   repair. The film was tested in vitro on rabbit corneal epithelial cells and keratocytes. The film showed its

428   effectiveness in promoting epithelial wound healing and inhibiting keratocyte-myofibroblast transformation,

429   which emphasizes CNC's potential to be applied as reinforcing agent material for corneal regeneration and

430   reconstruction. A film based only on CNC can also be applied for medical purposes. As the study by (Prathapan

431   et al., 2018) affirmed, the researchers prove the ability to use CNC film for blood typing. Despite all these

432   advantages, the nanotoxicity of CNC needs to be more investigated since some studies reported some possible

433   CNC toxic outcomes (Seabra et al., 2018).

434   **5.   Summary**

435   Cellulose is the most abundant biopolymer that can replace petroleum-based materials that harm health and the

436   environment. CNC can be extracted from native cellulose and is known for its important mechanical properties

437   (similar to Kevlar), surface reactivity, and its ability to self-assemble. Chemical modification of CNC broadens its

438   application in different domains of material science and enhances its compatibility with other materials.

439   Developing film and membrane based on CNC or modified CNC is a good solution to minimize the use of non-

440   biodegradable material. These films and membranes could be used in various applications such as biosensors,

441   electrodes, and membranes for water treatment, to name a few. Developing composite material from CNC could

442   provide solutions to a broad range of technological bottlenecks in the industry and replace toxic materials currently

443   being banned from use due to their impact on human health and environmental issues.
