We propose a formal and practical framework for defining and implementing a new constraint logic programming language over sets called Conjunto The main motivation for this work was to overcome current problems in solving set-based combinatorial search problems A set in Conjunto is constrained to range over a so called set domain specified as a set interval. Until recently, most work on embedding sets in logic programming and constraint logic programming has focused on set constructors and complete solvers These approaches aimed at exploiting the expressiveness of sets Our study of these languages came to the conclusion that complete solvers have severe efficiency problems due to the nondeterministic nature of set unification.

Set-based search problems are modelled in the language as set domain constraint satisfaction problems in which the nodes are variables ranging over a set domain and the arcs are set constraints In addition it provides a set of additional constraints, namely the graduated constraints, which define a relation between sets and integers or integer domains. We are thus able to deal with set-based optimization problems which apply cost functions to quantifiable, *i.e.* arithmetic, terms, while working on sets.

Conjunto has been implemented using a constraint logic programming plat form. The constraint solver is based on consistency techniques: a set of transformation rules perform interval reasoning over the domain bounds to infer local consistency. For efficiency reasons, completeness of the solver has been given up. The solver is described as a transition system checking one constraint at a time

The formal framework describes how elements from the computation domain *i.e.* the class of definable sets, can be approximated by elements from the constraint domains (set intervals), computations are performed its performed \sim describes the approximations and closure operations guaranteeing that any com putable solution lies in the approximations

The practical viability of the language is demonstrated by a set of applica tions from operations research and combinatorial mathematics They show the ability of the language to model set based problems in a natural and concise way while keeping the solving process efficient. Therefore they show that the trade-off between expressiveness and efficiency proposed in this thesis leads to a practical system

Motivation

Once upon a time there was a big universe called a universal set formed by the union of subparts or subsets The least element of the universe was a black hole which was so dense that it could contain hardly anything. Subsets of the universe could contain arbitrary elements A system built from this universe was based on various relations applied to the subsets. The satisfiability of the system was a crucial issued but it could be partially ensured by the local consistency of the dened relations and this could be done independently of the nature of the subset elements. This allowed us to reason about the subsets of the universe at a reasonable cost. The powerset lattice is the mathematical term for the structure of this system

This thesis proposes a new means to tackle set based combinatorial search problems in a constraint logic programming framework The main contribution of the work is a new constraint logic programming language allowing set based constraint satisfaction problems to be modelled and solved in an elegant way We introduce the notion of set domain following the concept of nite integer domain Fik The elements of a set domain are known sets containing arbitrary values and the set domain itself represents a powerset. It is defined as a set interval specified by its lower and upper bounds. The constraints of the language are built-in relations applied to variables ranging over set domains. The solver is based on an extension of constraint satisfaction techniques — originating in artificial intelligence— to deal with set constraints.

Domains in CLP

Logic programming $[Kow74][CKC83]$ [Llo87] is a powerful programming framework which enables the user to state nondeterministic programs in rela tional form. In the recent years, the concept of finite domain $[HD86]$ *i.e.*, set of natural numbers, has been embedded in logic programming to allow for efficient tackling of combinatorial search problems modelled as Constraint Satisfaction Problems CSP Mac A CSP is commonly described by a set of variables ranging over a set of possible values the domains and a set of constraints ap plied to the variables It is well know that combinatorial search problems are \mathcal{NP} -complete [PS82]. The solving of a CSP is based on constraint satisfaction techniques [Mac77][MF85] . They are preprocessing techniques aiming at pruning the search space, associated to a CSP, before the search procedure (eg. backtracking starts There are two dierent uses of these techniques in logic programming coming from two distinct motivations One consists in programming CSPs and

constraint satisfaction techniques at a meta level with respect to a logic pro gramming language $[RM90][MR93]$. This approach shows how to use logic programming for solving CSPs and how to transform logic programs using constraint satisfaction techniques. The second aims at extending a logic-based language with constraint satisfaction techniques at the language level [HD86]. This has led to the rst development of a \mathcal{L} and \mathcal{L} are \mathcal{L} . In the constraint \mathcal{L} nite domains Chip Daniel In Province In Prology In Prology, In Property In Prology,

CHIP extends the application domain of logic programming to the efficient solving of combinatorial search problems Typical examples are scheduling appli cations, warehouse location problems, disjunctive scheduling, cutting stock, etc [DSH88a] which come from artificial intelligence or operations research. The success of CHIP prompted the development of new finite domain CLP languages, classied as CLP FD languages but also raised the question of its limitations Some of the limitations are concerned with the diculties CLP FD languages have to model and solve a class of combinatorial problems based on the search for sets or mapping objects. Set partitioning, set covering, matching problems are such combinatorial search problems The main motivation of our work is to provide an elegant solution to this problem. So far, a finite domain CSP approach models a set either as a list of variables taking their value from a approach models a set either as a list of variables taking their value from a
finite set of integers $([x_1, ..., x_n], x_i \in \{1, 2, 3, 4\})$, or as a list of 0-1 variables matriangleright integers $([x_1, ..., x_n], x_i \in \{1, 2, 3, 4\})$, or as a list of 0-1 variables $([y_1, ..., y_m], y_i \in \{0, 1\})$. The first approach requires the removal of order and multiplicities among the elements of the list, which is achieved by adding ordering construction $\{x\}$, $\{x\}$, $\{x\}$, $\{y\}$, $\{x\}$, $\{y\}$, $\{x\}$, $\{x\}$, $\{x\}$, $\{x\}$, $\{y\}$, $\{y\$ arithmetic constraints. This is not natural, costly in variables, and this often makes the program non-generic. The second approach, based on the use of 0-1 \mathcal{L} is a set of the set of \mathcal{L} integer Linear Programming \mathcal{L} is a set of the set of use of the one-to-one correspondence which exists between a subset s of a known set S and a boolean algebra. This correspondence is defined by the characteristic function

$$
f: y_i \longrightarrow \{0, 1\}, f(y_i) = 1
$$
 iff $i \in s, 0$ otherwise

In other words, to each element in S a 0-1 variable is associated, which takes the value 1 if and only if the element belongs to the set s . This approach requires a lot of variables In addition it does not ease the statement of set constraints such as the set inclusion because the inclusion of one list into another requires considering a large amount of linear constraints over the 0-1 variables. This is not very natural, nor concise. To cope with this problem, two solutions have been proposed. One consists in defining a class of built-in predicates, referred to as global constraints $[Bel90a][BC94]$, which allow for concise statement and global solving of a collection of constraints One way to achieve such a global reasoning is to use operations research techniques in a CLP setting This approach aims both

at providing a better pruning of the variable domains by taking into account sev eral constraints at a time. It also extends the programming facilities of $CLP(FD)$ languages to handle efficiently specific problems such as the disjunctive scheduling the computation of circuits in a graph etc The second solution presented in this thesis aims at extending the expressiveness of the language to embedding sets as objects searched for and to provide set and mapping constraints for general purposes This requires investigating how CLP languages based on sets tackle the set satisfiability problem and how well expressiveness can be combined with efficiency.

Sets in LP and CLP

Most of the recent proposals to embed sets as a high level programming ab straction assume a logic-based language as the underlying framework. This is a result of the declarative nature of logic programming which combines well with set constructs, and from its nondeterminism which is suitable for stating setbased programs For instance a pure logic programming language is adopted in [BNST91] [Kup90] [DOPR91] [STZ92], an equational logic language in [JP89], and a CLP language in [Wal89] [LL91] [DR93] [BDPR94]. Constraint Logic Pro- α instances, α in as instances, α in a instance as instances of α instances α of the CLP scheme [JL87] over a specific computation domain describing the class of allowed sets and set constructs CLP combines the positive features of logic pro gramming with constraint solving techniques The concept of constraint solving replaces the unification procedure in logic programming and provides, among others, a uniform framework for handling set constraints $(\text{eg. } x \in s, s \subseteq s_1, s = s_2).$

The various CLP case is a modelling at modelling and prototyping set based on the set of the set of the set of problems in a natural and concise manner They deal with extensional sets de problems in a natural and concise manner. They deal with extensional sets de-
fined by a set constructor (eg. $\{x\} \cup S,$ $\{x_1,...,x_n\})$ such that the set equality is either Associative Commutative and Idempotent ACI LL or commutative and right-associative $[DR93]$. These properties are defined by axiomatizing a set theory. Regarding the set satisfiability problem, it is $N \mathcal{P}$ -complete or even $N \mathcal{P}$ hard [LS76] [PPMK86] [KN86] [Hib 95], depending on the class of axioms and predicates considered In addition the satisfaction of the ACI axioms introduces non determinism in the unification procedure itself. Each of these languages provides a sound and complete solver. This infers that the complexity of solving set problems in exponential and that the resolution procedure is equivalent to ap plying an exhaustive search procedure when solving an \mathcal{NP} -complete problem In \lfloor LLLH95 \rfloor , variables in a set $\{x_1, ..., x_n\}$ can range over nifile domains, and the solver makes use of consistency techniques to prune the domains This prun

ing is rather weak since the satisfaction of the ACI axioms introduces another source of non determinism. This prevents us from pruning the search space before the search procedure starts. This lack of efficiency is not a limitation when we take into account the objective of these languages, namely dealing with theorem proving $[DR93]$ or combinatorial problem prototyping $[LL91]$, but it is a problem when from prototyping we move to problem solving.

To achieve a better efficiency, the nondeterministic set unification procedure of constructed sets should be replaced by a deterministic procedure over sets represented as variables. In addition, sets should range over domains so as to make use of preprocessing techniques such as constraint satisfaction techniques To achieve this, we propose a language which enables us to model a set-based problem as a set domain CSP —where set variables range over set domains—, and which tackles set constraints by using constraint satisfaction techniques A set domain can be a collection of known sets like $\{\{a,b\},\{c,a\},\{e\}\}$. It might happen that the elements of the domain are not ordered at all, and thus if large domains are considered, it is not possible to approximate the domain reasoning by an interval reasoning as in some \mathcal{L} reasoning \mathcal{L} . To cope with this we propose to cope with this we propose to cope with this we propose to cope with the system of \mathcal{L} approximate a set domain by a set interval specified by its upper and lower bounds. thus guaranteeing that a partial ordering exists This allows us to make use of constraint satisfaction techniques by reasoning in terms of interval variations when dealing with a system of set constraints. The set interval $\{\{\},\{a,b,c,a,e\}\}$ represents the convex closure of the set domain above

The strengths of handling intervals in CLP have recently been proved when dealing, in particular, with integers and reals. On the one hand, interval reasoning does not guarantee that all the values from a domain are consistent, versus domain reasoning. On the other hand, it removes at a minimal cost some values that can never be part of any feasible solution This is achieved by pruning the domain bounds instead of considering each domain element one by one Interval reasoning is particularly suitable to handle monotonic binary constraints (e.g. $x \leq y$, $s \subseteq$ still where it guarantees the corrections beek there is domained available components while being more efficient in terms of time complexity.

Intervals in CLP

The introduction of real intervals into CLP aims at avoiding the errors result ing from finite precision of reals in computers. A real interval is an approximation of a real and is specified by its lower and upper bounds. It does not denote the set of possible values a variable could take but a variation of an infinite number of values. Cleary [Cle87] introduced a relational arithmetic of real intervals in logic programming based on the interpretation of arithmetic expressions as relations. Such relations are handled by making use of projection functions and closure operations which correspond to the denition of transformation rules ex pressing each real interval in terms of the other intervals involved in the relation These transformation rules approximate the usual consistency notions [Mac77]. The handling of these rules is done by a relaxation algorithm which resembles the arc-consistency algorithm $AC-3$ [Mac 77]. This approach prompted the development of the class of \mathcal{A} formalization of this approach is given by \mathcal{A} in $[Ben95]$.

which case (see clearly sharp make use the constraint satisfaction technical technical satisfaction of \mathbb{R}^n niques they do not model CSPs because the solving of a problem modelled in a CLP Intervals language searches for the smallest real intervals such that the computations are correct It guarantees that the values which have been removed are irrelevant, but does not bound the real variables to a value. On the one hand. set intervals in constraint logic programming resemble the real interval arith metic approach in terms of interpreting set expressions as relations and using interval reasoning to perform set interval calculus when handling the constraints We make use of similar projection functions which are the only way to handle set expressions (e.g. $s \cup s_1, s \cap s_1$) as relations. We also approximate the set domain of a set expression by a convex interval. On the other hand, set intervals in constraint logic programming contribute to the definition of a language which allows one to model and solve discrete CSPs in the CLP framework. In practice, this corresponds to providing a labelling procedure in order to reach a complete solution. Regarding optimization problems, it is necessary to allow the definition of cost functions which necessarily deal with quantifiable, *i.e.*, arithmetic, terms. This requires the definition of a class of functions, interpreted as constraints, which map sets to integers to integers \mathbf{r} and a cooperation between \mathbf{r} two solvers (set solver and nite domain solver solver). Solver and parameters dier from the from the solver of that is a complete that j differences where the complete issue is still and the complete problem because of the infinite size of real intervals.

Short outline

Part I- Sets and Intervals in CLP languages.

This part has three sections. Section 1 presents the constraint logic programming scheme and its operational model. Section 2 presents the class of $CLP(Sets)$ languages, with a particular attention given to the relationship between their application domains and their constraint solvers. Section β surveys consistency notions and algorithms and describes their embedding into the class of $CLP(FD)$ and clear (see called and control of \mathcal{A}

Part II- The Language.

This is the central part of the dissertation. This part contains three main sections. Section \ddot{A} describes the formal framework of a constraint logic programming language over set domains. It comprises the description of the system, that is the constraint domain —over which set interval calculus is performed— and the operational semantics. Section 5 describes the CLP language over set domains, called Conjunto, which we have designed and implemented using the constraint logic programming platform ECLTS | ECR94|. This section shows now constraint satisfaction techniques can be adapted to deal with constraints over set intervals using interval narrowing techniques. Section θ presents applications developed in Conjunto The applications illustrate the modelling facilities of the language and its ability to solve in an efficient way large problems. Comparative studies are made with finite domain CSP approaches.

Conclusion

In this part, we give an evaluation of the results achieved, present the related lines of work and discuss further possible research in terms of improving the current kernel and designing further extensions

Part ^I

Sets and Intervals in CLP Languages

1

Constraint logic programming is a relatively new programming framework  which aims at extending the applicability of logic programming to mathematical calculus set calculus set calculus set calculus set calculus set calculus etc. In the calculus etc. In the cal dense a class of languages class (i.e., parameterized by the computation domains of the computation of the c $X \cup \{X\}$ programming scheme, the constraint solving paradigm, and gives a short overview of the computation domains which currently exist

1.1 A logic-based language

A Constraint Logic Programming CLP language is a logicbased language that is a non-that is a nondeterministic product of the community of the community of the community of the community language where procedures are defined in a relational form. The syntax of a CLP program is that of a logicbased program based on a collection of Horn clauses [L lo 87].

Definition 1 A Horn clause is a disjunction of atoms with at most one nonnegated atom

$$
(Q_1 \vee \neg P_1 \vee \dots \vee \neg P_n)
$$
 or $(Q_1 \leftarrow P_1 \wedge \dots \wedge P_n)$

where Q_1 and the P_i are atoms and the variables appearing in the atoms are assumed to be universally quantified.

The declarative interpretation of a Horn clause corresponds to

 \sim 1. The state is the properties of P - P

A program goal is a clause of the form: \leftarrow G₁,G₂,...G_n where the G_i are atoms

To distinguish atoms from constraint relations a CLP program is formally defined by a collection of rules of the form

$$
Q_1 \leftarrow C_1 \land \dots \land C_n \Diamond P_1 \land \dots \land P_m
$$

where Q_1 is an atom, the P_i are atoms and the C_i are constraints. A goal is a collection of constraints and atoms, and corresponds to a rule without head, here without Q_1 .

1.2 The CLP scheme

The CLP scheme defined by Jaffar and Lassez [JL87] describes a formal semantics which subsumes logic programming. CLP defines a class of languages parameterized by their computation domain A CLP language is characterized by its computation domain its set of allowed constraints and its constraint solver The CLP scheme defines the following properties to be satisfied by a constraint logic programming language \mathcal{L} is an instance of the scheme of the s

Let us consider the computation domain $\mathcal D$ and the set $\mathcal L$ of constraints. The structure (ν , ι) describes the constraint domain over which constraint solving is performed. This structure must have a compactness property which guarantees that every element from the underlying computation domain is finitely definable using the constraints of the constraint domain. Consider a theory $\mathcal T$ which axiomatizes some of the properties of constraints in $\mathcal L$ applied to elements from D . The formal semantics defined in the CLP scheme describes the algebraic semantics of the language and its correspondence with the logical semantics. Jaffar and Lassez introduced new concepts to deal with the constraint domain structure and the theory which are the ones of *solution-compact* structure and a *satisfaction* complete theory

Definition $\boldsymbol{\Sigma}$ A structure $(\boldsymbol{\nu}, \boldsymbol{\mathcal{L}})$ is solution-compact if every element in $\boldsymbol{\nu}$ is the unique solution of a finite or infinite set of contraints in L , and every element \bar{L} in the complement of the solution space of a constraint c belongs to the disjoint solution space of some finite or infinite family c_i of constraints.

The correspondence between the theory $\mathcal T$ and the computation domain $\mathcal D$ aims at ensuring that $\mathcal T$ and $\mathcal D$ correspond on the satisfiability of elements from $\mathcal L$ and that every unsatisfiable constraints in $\mathcal D$ is also detected by $\mathcal T$. This is defined by the three following conditions

- \bullet $\mathcal D$ is a model of $\mathcal T$.
- for every constraint $c \in \mathcal{L}, \mathcal{D} \models \exists c$ iff $\mathcal{T} \models \exists c$
- T is satisfaction-complete with respect to $\mathcal L$ if for every constraint $c \in \mathcal L$, c *i* is *satisfaction-complete* with respect to *L* if for ev
is either provably true or false $\mathcal{T} \models \exists c$ or $\mathcal{T} \models \neg \exists c$.

If we consider a CLP program P and a goal G , the logic programming inference mechanism searches for a substitution σ such that $G\sigma$ (possibly infinite set of instances in the logical consequence of α consequence of a program, provided it is also a logical consequence of the theory T. Considering the C_i as a conjunction of constraints, we have:

$$
P, \mathcal{T} \models \forall (C_1, C_2, ..., C_n \Rightarrow G)
$$

The satisfaction-complete property of the theory plays a role in the completeness of the constraint solver. In practice it turns out that efficient constraint solving methods over certain structures cannot be combined with completeness of the solver Indeed as soon as the satisability problem over a computation do or the solver. Indeed, as soon as the satismability problem over a computation do-
main (eg. finite domains, sets) is an \mathcal{NP} -complete problem, the special purpose constraint solver will necessarily take exponential time to guarantee complete ness of the satisfaction procedure. For efficiency reasons, some solvers achieve a partial constraint solving based on consistency techniques These solvers will be subsequently described

Recently, Saraswat et al. [SRP91] proposed a generalization of the CLP scheme which defines the framework of concurrent constraint programming. It is based on two operators ask & tell which correspond respectively to constraint entailment and contraint statement actions. This framework has been adapted by Van Hentenryck and Deville to formalize the incompleteness of some constraint solvers dealing with linear constraints over finite domains [HD91] [HSD93].

1.3 Constraint solving

 CLP is a generalization of LP where unification $-\text{the basic operation of } LP$ languages— is replaced by constraint solving techniques. With regard to the constraint solving mechanism of a CLP program, Colmerauer [Col87] defined a general operational semantics which establishes an analogy with the SLD-resolution procedure embedded in LP. The SLD-resolution takes as input a set of clauses. It unifies the expressions, stores a sequence of substitutions and returns as output the successful substitution The resolution of CLP goals replaces unication by constraint solving and returns as output a set of satisable constraints It can be defined as a transition system on states comprising goals and constraints. Each transition rule can be interpreted as a rewriting process which derives a new state from the previous one. A solution is found when the final state does not contain goals to be solved. In case the set of constraints is not satisfiable, the resolution fails

One computation step of the constraint resolution procedure can be repre sented by analogy with one SLDderivation step as follows C-LO are sets of the SLDderivation step as follows Cconstraints G-constraints G-constraints and a one predicate It is depicted in the predicate It is depicted in in the figure 1.1 .

from $\leftarrow C \diamond G$ and $a \leftarrow C_1 \diamond B$ inier \leftarrow $\cup_2 \vee \cup \cup \cup D$) if merge $(\{\uparrow G \cup B\})$
if merge $(\{\uparrow G = a\} \cup C_1 \cup C)$ into C_2

 \pm G represents the first left atom in G, \pm G represents the remainder (cf. [Con90])

Figure 1.1 Constraint Solving: one resolution step

The merge function is the essential one in the solver It checks that the new constraints related to the goal are satisfiable in conjunction with the current ones. If this new set of constraints is not satisfiable the procedure fails, otherwise it returns the simplified set of constraints. This approach was originally defined for the CLP language Prolog III $\lbrack \text{Col87} \rbrack$ $\lbrack \text{Col90} \rbrack$.

However this function, which embeds two actions (satisfiability checking and simplication process can not be applied for constraint solvers that only ensure partial constraint solving and make use of delay mechanisms (where a constraint is neither considered satisable nor simplied Consequently it can not be gen eralized to any special-purpose constraint solver. Several operational models have been defined for specific constraint domains. Jaffar and Maher [JM94] proposed a fairly general framework also based on the transition system on states, but which splits the merge function into several functions each of which derives dis tinct transitions corresponding to a resolution simplication an addition of new constraints, a consistency checking, etc. It also distinguishes between active and passive constraints The active constraints are those which can lead to simpli fications, and the passive ones are those which can only be checked, but might become active once they are completely solved

Constraint domains 1.4

Various computation and more exactly constraint domains have been investigated in recent years but only some of them will been mentioned here A more detailed description can be found in [JM94]. The most widely known are:

- \bullet Linear rational arithmetic (UHIP [DSeass], Prolog III [Cols*t*], Prolog IV $|{\rm B}1\,30|)$ and real arithmetic $|{\rm ULP}(|{\cal K})| |{\rm JM}84|)$. Their solvers are based on the simplex algorithm, generalized to take into account handling of disequations and incrementality of the solving
- \bullet -boolean algebra (UHIP, Prolog III), whose solvers are based, respectively, on Boolean unification and on a combination of the SL resolution and saturation.
- \bullet -Linear arithmetic over finite domains (UHIP and others), whose solver is based on consistency techniques
- \bullet Real intervals (eg. BNR-Prolog [OV90], ULP(BNR) [OB95], interlog in a chip is a chip and the line of the line and the solven adapted and the solvers adapted the solve of the s consistency techniques to perform interval reasoning
- \bullet set calculus ({log} |DOPR91| |DR95|, ULPS |LL91|) and regular sets $\text{[CLP1] = [Walo9]}.$ These languages aim at guaranteeing the soundness and completeness of their respective solvers. They deal with set constructs, and provide a collection of allowed set operations and constraints

The last three constraint domains which have some common points with our work are presented in the next two sections

 $\overline{2}$

Most of the recent proposals to embed sets as a high level programming abstrac tion assume a logicbased language as the underlying framework It follows from to the declarative nature of logic programming which well combine with set con structs, and its nondeterminism which is suited to stating set-based programs. This chapter describes the class of \mathcal{L} and \mathcal{L} and \mathcal{L} and \mathcal{L} straint logic programming. Particular attention is put into the description of the computation domains and the constraint solvers of $CLP(\Sigma^+)$ which deals with regular sets, $\{log\}$ (reviewed from a LP to a ULP point of view) which axiomatizes a set theory and CLPS which aims at prototyping combinatorial problems using sets, multisets and sequences.

2.1 $CLP(\Sigma^*)$

ULP (2) T (Walog) represents an instance of the ULP scheme over the computation domain of regular sets. A regular set is a finite set composed of strings which are generated from a ninte alphabet \vartriangle . ULP (\vartriangle) has been designed and implemented to provide a logic-based formalism for incorporating strings into logic programming in a more expressive manner than the standard stringhandling features (eg. concat, substring). A \cup LP(\vartriangle) program is a Prolog program enriched with regular set terms and built-in constraints.

Operations on regular sets comprise concatenation RR- disjunction or union $R_1 + R_2$ (*i.e.*, $R_1 \cup R_2$) and the closure operator R_1 which describes the least set R such that $R = \epsilon + (R, R_1)$. These operations allow us to build any regular expression when combined with the identity elements under concatenation (1) and union (ψ) . This language provides an atomic constraint over set expressions which is the membership constraint of the form x in e where x is either a variable or a string and e is a regular expression. For example A in (Λ , \overline{a}) \overline{a}) states that any string assigned to variable A must contain the substring ab .

Overview of the solver The constraint paradigm allows to replace the unification procedure by constraint solving in the computation domain The satisability of membership constraints over regular sets clearly poses the problem of termi nation. In the above example, if Y is a free variable there is an infinite number of instances for A The solver guarantees termination by i applying a scheduling strategy which selects the constraints capable of generating a finite number of instances in a satisfact on determinant procedure and an order that the satisfact on deduction \sim check and transform the selected atomic constraints The non selected ones are simply floundered.

The selected constraints x in e are such that either e is a string or e is a variable and x a string. The conditional deduction rules over each of these constraints infer a new constraint or a simplified one if a given condition is satisfied. Each condition represents a possible form of selected set constraints

$$
\begin{pmatrix}\nw = w_1.w_2 \\
\sigma_1 \vdash "w_1'' \text{ in } e_1 \\
\sigma_2 \vdash "w_2'' \text{ in } e_2\n\end{pmatrix}
$$
 and
$$
\begin{pmatrix}\n\sigma_1 \vdash X_1 \text{ in } e_1 \\
\sigma_2 \vdash X_2 \text{ in } e_2\n\end{pmatrix}
$$
\n
$$
\overline{[X = (X_1\sigma_1).(X_2\sigma_2)] \vdash X \text{ in } e_1.e_2}
$$

The σ_i are idempotent substitutions, which means that given two substitutions σ_1 and $\sigma_2, \sigma_1 \cup \sigma_2$ produces the most general idempotent substitution if one exists that is more specific than the two previous ones.

Soundness and completeness of the deduction rules are guaranteed only if there are no variables within the scope of any closure expression e in addition $\overline{}$ to the criteria of constraint selection

This approach constitutes a first attempt to compute regular sets by means of constraints like the membership relation The complexity of the satisability procedure is not given, but infinite computations are avoided thanks to the use of floundering.

2.2 CLPS

The CLPS [LL91] [LL92] language is a CLP language based on a three sorted logic. The three sorts correspond to sets, multi-sets and sequences of finite depth (eg. $s = \{ \{ \} \in \mathcal{A} \}$, $c \}$ is a set of depth three). The concept of depth is equivalent for each sort Atomic elements can be any Herbrand term arithmetic expression or integer domain variable Set expressions are built from the usual set operator symbols $\cup, \cup, \times, \#$). Set variables are constructed either iteratively by means of the set constructor $\{x\} \cup s$ or by extension by grouping elements within braces

(eg. $\{x_1, ..., x_n\}$). The language also embeds nifile integer domains and allows set elements to range over a nite domain- Sequences and multisets are built using respectively, the constructors $sq\{...\}$ and $m_1...\}$. Basic constraints (implemented in the language) are relations from $\{\in, =, \notin, \neq, \setminus\}$ interpreted in the usual mathematical way together with a depth and a type checking operator- Note that set equality relation sould be associative commutative and idempotent- These properties are species to the ACI state of the ACI notation of the ACI notation of the ACI notation of the ACI

The satisfiability problem for sets, sequences and multisets is \mathcal{NP} -complete LS - To cope with this CLPS provides several methods whose use depends on the characteristics of the CLPS program at hand-

Overview of the solver The CLPS solver makes use of various techniques comprising: (i) a set of semantical-consistency rules, (ii) an arc-consistency al- Ω combined with a local search procedure for Ω checking, where $\{1,2,3,4\}$ is checked transformation procedure-the contract the contract the contract the contract of \mathcal{A} sistency of each set constraint with respect to homogeneity of types, depth and cardinality-beneficially-beneficially-beneficially-beneficially-beneficially-beneficially-beneficially-beneficially-

$$
\{x\} = \{y, z\}
$$

is semantically-consistent if $y = z$.

A semantically-consistent system of set constraints is then solved in two stages. The solver rst divides the system in two independent subsets- One written $S \subset \mathfrak{g}$ contains set constraints whose constrained sets are sets of integer domains $\mathbf{v} = \mathbf{v}$ set elements are free values- or known values- resolver applies of the solver applies in the solve respectively to check satisfies $\lim_{n\to\infty} \int u \, du$ and $\sum v_i$.

 \bullet A system SU_{fd} is consistent if each of the set constraints it contains is arc consistent-the production of the domains α is achieved by removing the domains of the domains of the domain set elements which cannot be part of any feasible solution- For example the set elements which cannot be part of any reasible solution. For example, the
above system is consistent if $x \in \{2,3\}$ and $[y, z] \in \{2,3\}$. Completeness of the resolution is guaranteed by the labelling procedure which performs forward checking combined with the rst fail principle- It amounts to assign ing a value to a set element from its domain and to inferring possible new domain modifications- to the activities of the Marian that due to the ACI property of the ACI property of the A erties of set equality distinct selected values for the elements will generate structed sets requires in the worst case an exponential number of choices structed sets requires in the worst case an exponential number of choices
to be made. The system $[x_1, ..., x_n] \in \{1, ..., m\}, \{x_1, ... x_n\} = \{1, ..., m\}$ corresponds to 2^{n-m} computable solutions.

 \bullet -A system SU_v is satisfiable if its equivalent integer linear programming form is satisable- To check satisability the system provides a correct and com plete procedure which transforms the set constraint system into an equiv alent mathematical model based on integer linear programming [HLL93]. This procedure consists in flattening each set constraint and reducing the system of flattened formulas to an equivalent system of linear equations and disequences over nite domain variables-system is the domain variable system is the derived system is the solve using consistency techniques- The attening algorithm works by adding ad ditional variables to reach forms from $(x = y, x \in y, x = \{x_1, ..., x_n\}, x =$ $y \cup z, \; x = y \cap z, \; x = y \setminus z,$ etc.). The reduction to finear form is performed by associating to each set variable α , which variable ω_{ab} which represents α its cardinality and to each pair of variables λ - wi-field variables λ - wi-field variables λ Qij denoting possible set equality constraints- If there are n constraints the complexity of the requation procedure is in $O(n^2)$ [HLL94] [H1D95].

The proposed solving methods are among the most appropriate for handling set constraints over construction constructed and language application domain of the language guage which aims at prototyping combinatorial search problem dealing with sets multisets or sequences- Unfortunately the nondeterminism in the unication of set constructs prevents an efficient pruning of the domains attached to set elements in case the focus is put on the domain variables is put on the focus is put on the expressive of the expression power of the language rather than on the efficient solving.

2.3 $\{log\}$

 $\{log\}$ [DR93] is an instance of the CLP scheme designed and implemented mainly for theorem proving- It embeds an axiomatized set theory whose properties guar antee soundness and completeness of the language-structure-are constructed are constructed and a using the interpreted functors with and $\{\}$, e.g. ψ with x with ψ with y with $z_1 = \{ \{2, \vee\}, \mathrm{X} \}$. The language includes a limited collection of predicates $\lambda \in \mathbb{R}$, \neq , $\#$) as set constraints. The axiomatized set theory consists of a set of axioms which describe the behaviour of the behaviour of the constructor \mathbb{F}_q extensionality axiom shows how to decide if two sets can be considered equal

v with $x = w$ with $y \rightarrow$ $x = y \wedge v = w \vee v \cdot x = y \wedge v$ with $x = w \vee v$ $x = y \wedge v = w$ with $y \vee z \vee v = z$ with $y \wedge w = z$ with $x \vee v = w$

Using the axioms a set of properties are derived describing the permutativity $(right$ associativity) and absorption of the with constructor.

For example, the permutativity property is depicted by:

 $(x \text{ with } y)$ with $z = (x \text{ with } z)$ with y (permutativity)

Overview of the solver The complete solver consists of a constraint simplification algorithm defined by a set of derivation rules with respect to each primitive comstrainted to constraint a derivation rule for the equality constraint is formed the constraint in

 h with $\{t_n, ..., t_0\} = k$ with $\{s_m, ..., s_o\}$

If h and k are not the same variables then select non-deterministically one action among

- $t_0 = s_0$ and h with $\{t_n, ..., t_1\} = k$ with $\{s_m, ..., s_1\}$
- \bullet $t_0 = s_0$ and h with $\{t_n, ..., t_0\} = \kappa$ with $\{s_m, ..., s_1\}$
- $t_0 = s_0$ and h with $\{t_n, ..., t_1\} = k$ with $\{s_m, ..., s_0\}$
- \bullet n with $\{t_n, ..., t_1\} = N$ with s_0, N with $s_0 = k$ with $\{s_m, ..., s_1\}$ otherwise select i in $\{0, ..., m\}$ and apply one action from another set of rules.

This non deterministic satisfaction procedure reduces a given constraint to a collection of constraints in a suitable form by introducing choice points in the constraint graph itself-constraint itself-constraint in the search growth in the search in the search tree, since in the worst case all computable solutions have to be investigated (if $s_1 = s_2$ and $\#s_1 = n$, there are 2^{∞} computable solutions). But completeness is required if one answer in performing theorem proving- recent theorem performance compromise here between completeness and efficiency.

A recent extension to the language introduces intensional sets in constraint logic programming BDPR- Allowing for set grouping capabilities the inten sional definition is handled by reducing the set grouping problem to the problem of dealing with normal logic programs i-e- programs containing negation in the body of the clauses.
Two classes of CLP languages deal with variables ranging over intervals and/or finite domains- The class of CLPF languages domains- α with α considers linear arithmetic over natural numbers as well as some symbolic con straints, provided that the variables take their value from a finite set of integers. They aim at modelling and solving constraint satisfaction problems in a con straint logic programming framework- The second class is that of CLPIntervals languages which deal with real interval arithmetic- The use of intervals is meant to approximate real numbers so as to avoid rounding errors- This chapter describes these two classes of languages, whose solvers are based on consistency techniques.

3.1 Constraint satisfaction problems

Formally, a Constraint Satisfaction Problem (CSP) is a tuple $\langle V, D, C \rangle$ where:

- V is a set of variables $\{V_1, ..., V_n\},\$
- \bullet D is a set of domains $\{D_1,...,D_n\}$ where D_i is the domain associated to the variable V_i ,
- \bullet C is a set of constraints $\{C_1,...,C_m\}$ where a constraint C_j involves a subset of the variables.

The constraint set in a CSP is such that each variable appearing in a constraint showled take its value from a given domain-domain-domain-domain-domain-domain-domain-domain-domain-domain-doma by a constraint network whose nodes are the variables with their associated do by a constraint network whose nodes are the variables with their associated do-
mains and whose arcs are the constraints. A CSP models $N\mathcal{P}$ -complete problems as search problems where the corresponding search space is represented by a Cartesian product space $D_1 \times D_2 \times ... \times D_n$ of the domains (cf. Golomb [GB00]).

3

3.2 Constraint satisfaction

The solution of a CSP is a set (or subset as noted in $MR93$) of variables assigned to one values and solving of a solving and all the specific α and a set of preprocessing methods referred to as consistency techniques and then applying some search techniques or labelling procedure- Consistency techniques aim at pruning the search space before a standard search procedure like backtracking is applied and thus at improving the average complexity of standard backtrack ing consider a search tree as the assemble as the assemble representation of any ing [Walbu][GB65]. Consider a search tree as the abstract representation of an
 $\mathcal N\mathcal P$ -complete problem where one branch is a combination of values. Backtrack \mathbf{f} and a feasible solution or all solution or all solution or all solutions of \mathbf{f} such problems using an exhaustive searching process. Process-Backers all mat the branches and stops searching one branch as soon as it encounters a failure-

Formally, the backtracking algorithm aims at finding a solution specified by a vector $(x_1, x_2, ..., x_n)$ with $x_i \in D_i$ such that it satisfies a set of constraints represented by a criterion function $\mathcal{X} \setminus \{0,1\}$ with $\mathcal{Y} \setminus \{0,1\}$ and criterion vector might not be unique, and it may suffice to find one such vector or be necessary to find all of the problem-depending on the problem-depending on the problem-depending on the problem-depending on \mathcal{A} (true or false). If a partial vector $(x_1, x_2, -, -, ..., -)$ is unacceptable, all possible solutions containing x_1 and x_2 can be ruled out without having to be considered individually-branch-branch-branch-branch-branch-branch-branch-branch-branch-branch-branch-branch-branch-branch-

Non deterministic algorithms are convenient representations of systematic search procedures but they turn out to be inecient for large problems- Ex haustive search combined with the thrashing¹ phenomenon leads in the general case to computations that are exponential in the size of the Cartesian product of the domains- A solution to this problem consists in removing inconsistent values before any attempt is made to include them in the sample vector- This prepro cessing step is achieved by consistency techniques-

The current consistency algorithms perform different degrees of preprocessing. Their behaviour amounts to going through the constraint network in a node driven way and checking among other methods, the consistency of each node , and arc archiveness of the construction of the construction of the second of the second construction of the c \mathcal{M} , and the length two monotonical contracts \mathcal{M} the contract of the contract of

The definitions of node, arc and path consistency are usually given for unary and binary constraints denoted respectively Pk xi-minimal particles and the state of the state of the state of does not prevent consistency techniques from being applied to n-ary constraints,

Thrashing means that some unacceptable values will be considered at several steps of the search even though they can never be part of any feasible solution-

since any in all, constraint can be expressed in terms of binary ones, the state in the state of the denitions of node arc and path consistency \blacksquare

Definition 5 A node i is node consistent if and only if for any value $x \in D_i$, $P_i(x)$ is true.

Definition 4 An arc (i, j) is arc consistent if and only if for any value $x \in D_i$ such that $P_i(x)$, there is a value $y \in D_i$ such that $P_i(y)$ and $P_{ii}(x,y)$.

 \blacksquare if a path of length m through the nodes i-modes i-mode consistent if and only if for any values $x \in D_{i_0}$ and $y \in D_{i_m}$ such that $P_{i_0}(x)$, $P_{i_m}(y)$ and $P_{i_0,i_m}(x,y)$ hold, there is a sequence of values $z_1 \in$ $D_{i_1},...z_{m-1} \in D_{i_{m-1}}$ such that:

 $\binom{9}{7}$ - $\binom{1}{1}$ and $\binom{2}{1}$ and $\binom{3}{1}$ and $\binom{2}{1}$ and $\binom{3}{1}$ an $i_{1}^{(1)}$ \cdots $i_{1}^{(m)}$ \cdots $i_{1}^{(m)}$ \cdots $i_{1}^{(m)}$ \cdots $i_{m}^{(m-1)}$ \cdots $i_{m-1}^{(m)}$ \cdots $i_{m-1}^{(m-1)}$ \cdots $i_{m}^{(m-1)}$

These definitions can be generalized to the notions of node, arc or path consistency of a constraint network which correspond to having every node arc or path \equiv in the corresponding directed graph consistent.

Algorithms

The node consistency algorithm checks that for each variable via \mathbf{r} and \mathbf{r} \mathcal{L} constraint \mathcal{L} is all the elements \mathcal{L} in its domain Di satisfy the constraint \mathcal{L} right is some elements do not satisfy the removed from the remove the removement from the satisfy domain Di - This algorithm is quite simple and requires a single pass through a single pa the unary constraints cf- Mac -

The various arcconsistency algorithms require more complex processing- They are based on the following observation (cf. [Fik(0]): *if for some* $x \in D_i$ *there is no* $y \in D_j$ such that $P_{ij}(x,y)$ holds then x should be removed from the domain D_i . This test should be done for each $x \in D_i$ to conclude if one arc is consistent or not-test resembles the criterion function function in backtrack programming, but it differs in that it does not choose a value x for a variable but it tests if this value is not deep control control with the assignment process is replaced by a test- Γ modied- the Review of the Review is a complete in the Review is the Review in the Review in the Review in the the kernel of current arc consistency algorithms-

```
procedure REVISE((i,j)):
begin
  DELETE \leftarrow falsefor each x \in D_i do
      If there is no y \in D_i such that F_{ii}(x, y) then
       begin
          delete x from D_i;
          DELETE \leftarrow true
       end
  return DELETE
end
```
Figure 3.1 REVISE procedure

Reveal and answer to whether the answer to whether a domain modification model was done to warranted a domain modification was approached a domain of the contract of the contract of the contract of the contract of the cont required to infer arc consistency of a binary constraint- When the arc consistency of the constraint network is concerned the process is more complicated- Indeed checking and arc jively distinguire replace records of the domain of j and consequently the domain \mathcal{A} the as yet consistent and it, j might not be consistent any mission where α opposed to the node consistency algorithm, arc consistency over a network can seldom be a single in a single pass through all the arcs-seldom point the various α arc consistency algorithms proposed so far dier- The problem is to reconsider as few arcs as possible for complexity and thus for eciency reasons- The various generic arc consistency algorithms developed so far are (the first three have been called AC-1 AC-2 AC-3 by Mackworth in $[MF85]$:

- \bullet $\rm AU$ -1 (embedded in the first constraint system REF-ARF $|\rm F1K/ U|$). This is the simplest algorithment is repeated passes the algorithm all the arcs each \sim time one domain is revised until there is no change on an entire pass- At this point this must be consistent with a problem the construction of \mathbb{R}^n obviously inefficient, because a single modification of the domain causes all the arcs to be revised, whereas only a subset of them might be affected.
- AC based in spirit on Waltzs ltering Wal - Noting the weaknesses of AC-1, Waltz's idea was that arc consistency can be achieved in one pass over all the nodes by taking into account the order of the nodes covered and by the money that when a node is considered in an architecture in an arc i-left in an architecture arcs (g, n) where $g, n \leq i$ must have previously been made consistent. The

crucial improvement is that when a node j is considered, all the arcs *leading* from it and to it may have become inconsistent and must be revised again-

- \bullet \bullet \bullet (proposed by Mackworth \vert Mac*tt* \vert). This approach moves from the no decree reasoning of AC to an arc direction reasoning-tensoring-tensoringstored in one queue and REVISE is applied to each of them sequentially-The basic idea consists in selection and removing and removing one arc i-from the moving one arc i-from the selection \mathcal{L} queue applying REVISE to it and if the answer is yes Di modied adding to the queue all those arcs $\{\{k,\ell\}\}$ that might need to be reconsidered. This algorithm is so far the principal one embedded in most constraint satisfaction solvers-solvers-and is description in the solver of the solver of the solver of the solver of the
- \bullet \bullet \bullet (proposed by Mohr and Henderson $|\bullet|$ and based on the techis developed in the constraint satisfaction system at $\mathbf 1$ while active arcs in the contract is a construction of the contract over an intervention of the contract of the handling domains of variables eg- Di - Dj to dealing with inconsistent val \mathcal{L} associated to one domain-the storing of a storing of a storing of \mathcal{L} counter which represents the number of possible values of j such that for each value $b \in D_i, \; (b, j)$ holds. This counter, associated to each string itit is decremented each time and the complete \mathcal{L} is decreased and arc e-fine \mathcal{L} The basic idea consists in handling the set of arcs $\{(i, c)\}\$ for each $c \in D_i$ as well as the number of values which are consistent with one specific value. This approach leads to the optimal arc consistency algorithm with respect to time complexity- However it might be costly in memory utilization due to the amount of information it has to maintain-
- \bullet \bullet \bullet (proposed by van Hentenryck and Deville $\rm[HD192]).$ In contrast to the previous algorithm, this one aims at reducing the time complexity by considering the semantics of the constraints at hand- It distinguishes pred icates according to their underlying properties (functional, anti-functional, monotonic etc---- While AC deals with arcs ic AC manipulates ele ments i- j-v where i- j is an arc and v is a value removed from Djwhich requires reconsideration of i- j- Optimal procedures for the class of functional, anti-functional and monotonic constraints have been proposed. The specific case of the monotonic constraints permits performing reasoning over the domain bounds only (assuming the domains are totally ordered). Like $AC-4$, $AC-5$ propagates unconsistent values, but instead of decrementing a counter attached to each possible value of one node it adds to the list of the elements all those which correspond to newly inconsistent arcs with respect to one values which interesting point in a line of a line of an and \sim only necessary information is propagated.

Complexity issues. Mackworth and Freuder show the complexity of AC-1, $\mathcal{L} = \mathcal{L} = \mathcal$ number of arcs and number of number of number of number of number of number of $\mathbf n$ given in terms of worst case time complexity-

 $*$ This complexity result assumes that the constraint network is connected (it \blacksquare implies $e \geq n - 1$.

 $**$ This time complexity can be reduced to $O(ea)$ for the class of functional, anti-functional and monotonic constraints, and their generalization to piecewise functional, anti-functional and monotonic constraints (see $[HDT92]$ for the definition of piecewise decomposition of constraints).

The following AC-3 algorithm is the one upon which most improvements and variations of arc consistency algorithms have been performed- The set of arcs in the constraint graph G is manufactory arcsG in an angular - construction

```
begin
    for i \leftarrow 1 until n do node consistency;
     for i \leftarrow 1 until n do node consistency;<br>
Q \leftarrow \{(i, j) | (i, j) \in \arcsin(G), i \neq j\}while Q not empty do
            begin
                select and deletect and any arc k-title and deletect and any state and developed any state of the selection of
                if REVISE k-
m then
                   REVISE ((k, m)) then<br>
Q \leftarrow Q \cup \{(i, k) \mid (i, k) \in \arcs(G), i \neq k, i \neq m\}end
end
```
Figure 3.3 AC-3 algorithm

Other approaches toward efficient algorithms are based on the study of the topology of the constraints graph itself (see present), presently a model of the methods have not been embedded so far in CLP solvers possibly because of the particular properties of the constraint graph they require —which are seldom those of a CSP program.

Search Techniques

While consistency techniques aim at filtering the domains before starting the search, the search techniques embed various degrees of arc-consistency within a standard backtracking procedure- They correspond to the notions of forward checking particle is checked and full looked and functional \mathcal{A} achieved by these search techniques ranges between that of backtracking and that of arc consistency-

Consider the initial description of the backtracking process, based on a Cartesian product space $D_1 \times D_2 \times ... \times D_n$, a solution or sample vector $(x_1,...,x_n)$ where $x_i \in D_i$, and a criterion function to be satisfied $\phi(x_1, ..., x_n)$. A step k in the computation is denoted $(x_1,...,x_k,-,...,-)$ which corresponds to having the particles to the constant $\{x \in T: x \in W\}$, where $\{x \in T: x \in T\}$

Forward checking. Whenever a value x_{k+1} is successfully added to the current state of the sample vector $(x_1,...,x_k,-,...,-)$ (*t.e.* we have $\varphi(x_1, ..., x_k, x_{k+1}, ..., -) = 1$, the domains $D_{k+1}, ..., D_n$ of all as yet uninstantiated variables are filtered to contain only those values that are relevant with this new instantiation-by instantiation-by the rule of t

 $\forall l \in \{k+2, ..., n\} \forall x_l \in X_l$ such that $\phi(x_1, ..., x_k, x_{k+1}, ..., ..., x_l, ..., ..., -) = 1$

If the domain of any of these uninstantiated variables becomes empty the con straint fails and backtracking occurs- to standard backtracking occurs- to standard backtracking a preprocessing step in which some irrelevant values are removed before they may . These values will come on the domain the domain of t able directly connected with x_{k+1} .

Full lookahead. Whenever a value x_{k+1} is successfully added to the current state of the sample vector $(x_1,...,x_k,-,...,-)$ the forward checking conditions must be satisfied and the domain of each variable —as yet uninstantiated— must be filtered, so that it should only contain those values which are relevant with respect to at least one value in all the domains of the variables they are connected with- This is described by the rule

 $\forall l \in \{k+1, ..., n\}, \forall x_l \in X_l$ such that: $\forall u \in \{k+1, ..., n\}, \forall x_l \in \Lambda_l$ such that:
 $\forall m \in \{k+1, ..., n\}, m \neq l, \exists x_m \in X_m$ which satisfies $\varphi(x_1, ..., x_k, x_{k+1}, -, ..., -, x_l, -, ..., -, x_m, -, ..., -) = 1$

The full lookahead method performs less pruning than arc consistency algo rithms because it performs one single pass through all the binary constraints- A consistent arc will never be reconsidered whatever new refinements of the domains of the variables involved may have been performed-

Partial lookahead. This method has been introduced by Haralick [HE80] to and the latering process achieved by the forward checking methodsome where in a basic idea is a checking and full lookahead-idea is the basic idea is and full look not to lter one Xl by considering all the other variables as yet uninstantiated but to consider only those that are ahead of Xl which falls as

 $\forall l \in \{k+1, ..., n-1\}, \forall x_l \in X_l$ such that: $\forall n \in \{k+1, ..., n-1\}, \forall x_l \in \Lambda_l$ such that:
 $\forall m \in \{l+1, ..., n\}, \exists x_m \in X_m$ which satisfies $\varphi(x_1, ..., x_k, x_{k+1}, -, ..., -, x_l, -, ..., -, x_m, -, ..., -) = 1$

3.3 Constraint satisfaction in LP

The solving of CSPs using Logic Programming (LP) has been investigated from two dierent perspectives- One proposed by Montanari and Rossi aims at den ing a CSP as a logic program and dening the constraint satisfaction or relaxation algorithm at a metal \mathcal{M} and \mathcal{M} are modelling that modelling that modelling \mathcal{M} CSPs and consistency algorithms in LP is adequate- It also shows how logic pro π and and simplicities in the simplicity π simplicities algorithms - π and π second approach aims at providing a language enriched with programming facilities so as to solve search problems in a way transparent to the user- This approach which led to the class of $CLP(FD)$ languages is presented here.

For a different purpose, constraint satisfaction techniques have been embedded in LP to deal with real intervalse to the corresponds to the class of CLPIntervalse to the class of CLPInterval languages based on approximations of reals using real intervals.

$CLP(FD)$

Van Hentenryck and Dincbas [HD86] embedded constraint satisfaction techniques into logic programming by extending the concept of logical variable to the one of domain-variables which take their value in a finite discrete set of integers.

The key idea is to introduce the domain concept inside logic programming- This requires extending the unification procedure to the case of domain variables, thus making it possible to handle constraints using consistency techniques as inference rules- In particular the search techniques forward checking lookahead and partial lookahead) have been embedded into logic programming as inference rules is that the idea is that the idea is that the way the wa be applied locally to specific constraints, thus allowing for the most appropriate solving method- For example the partial lookahead inference rule deals eciently with animal expressions involving \mathcal{L} are \mathcal{L} and \mathcal{L} are variables and \mathcal{L} and \mathcal{L} are \mathcal{L} amounts to reasoning over domain bound variations- and the given bound variation of the first finite domain constraint logic programming language CHIP (Constraint \mathbf{A} and \mathbf{A} are arithmetic equations in the article equations in the arithmetic equations in the set of \mathbf{A} and disequations over natural numbers as well as some symbolic constraints-

This "clever" manipulation of constraints which leads to efficient pruning with respect to one constraint follows the basic idea of earlier solvers for CSPs like avec convergence is a community programministic programming the conduction of α language accepted by the problem solver ARF- The solver is based on the notions of node and arc consistency- In ALICE the constraints are expressed in a mathe matical language based on relation theory and some notions of graph theory- The searched ob jects are functions which should satisfy a set of constraints- The solver combines a depth-first search method with sophisticated constraint manipulation techniques and a set of powerful heuristics- The lack of exibility of these seminal systems both in the language representation and the solving strategy motivated the design and implementation of CHIP-

The success of CHIP in the solving of a large class of combinatorial search problems like car-sequencing, warehouse location, investment planning, etc. μ DSH δ 81 μ DSH δ 80 μ DHS δ 88 μ Hensit started the development of new nittle domain CLP languages based on new features and implementations- The basic dif ference is that the user is not able any longer to specify how to use constraints unless they are userdened constraints- Most of the systems solve the constraints using some local transformation rules based on consistency notions which are han die by a relation regulation resembling as due to all the contract of the contract of the contract of the contr suspension handling coroutines to wake the constraints which have to be recon sidered.

Later systems include $ECL^{i}PS^{e}$ based on the notion of attributed variables [Hui90][Hol92] and a suspension mechanism which handles the delay and wakening of goals and constraints- It provides the features necessary to allow a user to develop his own constraints solver a specie computation domain-domain-solver over a specie of \mathbb{R}^n [HSD93] is another successor of CHIP based on the AC-5 arc consistency algo-

rithm. This language is denned as an instance of the cc framework over finite domains-to-the nite domains-to-the nite domain library of CHIP a set of additional general general general gen purpose combinators (such as cardinality, implication, constructive disjunction).

The early designers of CHIP also developed a new version CHIP V4 which includes a set of new global constraints \mathbf{B} at reasoning globally over a set of constraints, versus local reasoning over one constraint- Recently some powerful techniques from operations research have been considered to increase the eciency of the solving- From a practical point of view they extend the application domain of the CHIP language to tackle efficiently graph and scheduling problems-

The finite domain library of CHIP has also given birth to a class of industrial languages like CHARME [OPL89], SNI-Prolog, Decision Power, ILOG solver $[Pug92][CP94]$ among others.

$CLP(Intervals)$

This class of languages embeds the notion of domain with a different meaning. A domain specified by an interval does not represent a set of possible values a variable could take but an approximation of a value- This research has been motivated by the errors resulting from finite precision arithmetic in computers. Each interval is marked by its lower and upper bounds which may or may not be included in the interval open and closed intervals- This approach has been rst implemented in Prolog from a functional viewpoint Bun- It provides correct information about the range of the functions but it prevents us from representing and the logical real variable and from solving equations equa not be solved).

. Clearly intervals in programming to avoid the weaknesses of the functional approach- The relational form of interval arithmetic is based first on the internal representation of reals as approximated intervals and second on the interpretation of arithmetic expressions as relations- This relational form can be nicely embedded into logic programming-Such a relation is specified as a subset of a Cartesian product of the real intervals in it-t-make sure that the approximated in it-t-make sure that the approximated intervals are the unique smallest ones which contain acceptable real values. Cleary makes use of projection functions and convex closure operations which allow the representation of each real interval appearing in a relation in terms of the other intervals which appear in the Cartesian product-closure operations and the complex \mathcal{L} is a complex \mathcal{L} is a complex \mathcal{L} is a complex \mathcal{L} is a complex of \mathcal{L} is a complex of \mathcal{L} is a complex of \mathcal{L} is a complex o puted intervals are convex that is they do not contain holes- They constitute

 \lceil concurrent constraint framework, cf- ask $\&$ $telt$ connectives

a second al level of approximation-to-contently some pro jections associated that induced to the multiplication relation, for example, do not necessarily derive convex intervals- Thus the derived disjunctions of intervals are approximated by a closed one-This approach which does not allow "holes" in the intervals, might infer that some values in the intervals are inconsistent but are kept to avoid manipulating unions of intervals-between a solution to this problem consisting in splitter in splitter in splitter in split ting the constructive inter the intervals and checking when the theoriting where some constant further restrictions can be deduced by performing nondeterministic computations over the disjunctive intervals.

. A relaxation algorithm based on Waltz ltering algorithm based on Waltz ltering algorithm \mathcal{A} processes a system of constraints by handling the various projection functions. It makes use of delay mechanisms to reconsider the relations whose Cartesian product has changed- The practical framework described by Clearly has been embedded in various languages referred to as CLPIntervals- to assemble them are \sim based on the relational form of interval arithmetic and the use of a relaxation algorithm to process a system of constraints- They do not handle the splitting of real intervals since it has been shown that handling disjunctions of intervals leads to a combinatorial explosion because of the large number of choice points which are generated once a disjunction is maintained and propagated.

A theoretical framework for the class of $CLP(Intervals)$ languages has been described in a scribe in the key notion of approximation of approximation of approximation of approximation and one of narrowing operators correct proportions which derive the choice the control est intervals from the previous ones so that the non relevant values are removed-The relaxation algorithm is referred to as the fixed point algorithm but provides the same constraint propagation and handling of the narrowing operators-

This class of $CLP(Intervals)$ languages differs from that of $CLP(FD)$ languages in the sense that an interval which is not reduced to one value might be a possible solving where \mathcal{L} solving where a domain is a set of possible where a domain is a set of possible \mathcal{L} values and a solution should contain only variables instantiated to one domain value- The notion of approximated reals is very much related to the correctness issues and does not aim at solving a CSP-

Part II

est au somme de tes de tes de tes de tes de tes que te que tu trouveras la réponse.

This chapter describes the formal framework of a constraint logic program ming language dealing with sets which range over a nite domain i-e- sets which belong to a powerset-to-a powerset-to-a powerset-to-a powerset-to-a powerset-to-a powerset-to-a powersetdomain and syntax of the language that consists of the usual set operations and relational symbols $(\cup, \cup, \setminus, \subseteq)$. The second step is the constraint solving part. The set satisfiability problem is $N\mathcal{P}$ -complete and thus partial constraint solving is required to the deterministic deterministic of completeness but in provincial complete and complete the focus is on the definition of the constraint logic programming system which performs local consistency techniques over constraints of the language- The main idea is to specify each set domain by a set interval and to check the consistency of the constraints using the interval reason in particular it is described it is described it is described in the con straint domain of the system should be structured so as to deal with set intervals-This requires, among other things, to approximate the domain of a set expression (which might contain "holes") by a set interval and to define a set interval calculus-then shown how computations are performed over the computations are performed over the constraints of domain using a top-down execution model.

A constraint logic programming language with sets, set operations and relations is not expressive enough to tackle set based search problems- In particular optimization problems require the statement of an optimization function which necessarily deals with quantiable i-e- arithmetic terms- To cope with this an extension of the language is presented and consists in adding to the language syn tax and to the constraint domain of the system a class of functions which map \mathbf{u} to integer experiment etc. The set weight etc. The set weight etc. are called graduations when they map elements from a lattice e-g- a powerset equipped with the operations \cup , it and the partial ordering \cup to the set of integers.

4.1 Basics of powerset lattices

Some definitions, properties and results on lattices are necessary to understand the main features of the formal language descriptions. These can be found in \mathbb{R}^n in \mathbb{R}^n present particular lattice we deal with the powers of the powers of the powerset with the powers of the powers give an intuitive idea of the subsequent use of these denitions some examples relating to powers familiar are given -these indicates these notions can also an skip this section.

Lattices

De-nition A poset also known as partially ordered set is a set S equipped with a binary relation \preceq (formally a subset of $S \times S$) that satisfies the following

 $F1.$ R e R exivity ∇x , $\forall x, x \preceq x$ PZ . Antisymmetry $(x \leq y \text{ and } y \leq x) \Rightarrow (x = y)$ P3. Transitivity $(x \preceq y \text{ and } y \preceq z) \Rightarrow x \preceq z$

Example 7 Let S be a finite set and $\mathcal{P}(S)$ the set of all subsets of S or powerset of S. Then the set inclusion \subseteq is easily seen to be a partial order on $P(S)$. $P(S)$ is a poset.

nition and nition and y an is a meet or greatest lower bound or glb for X iff:

y is a lower bound for Λ , i.e., if $x \in \Lambda$ then $y \preceq x$ and, if z is any other lower bound for X then $z \preceq y$

The notation we use is $y = \Lambda(X)$.

Definition 9 Let S be a poset, $A \subseteq S$ and $y \in S$. Then y is a join or least upper bound or lub for X iff:

y is an upper oound for Λ , i.e., if $x \in \Lambda$ then $y \succeq x$ and, if z is any other upper bound for X then $z \succeq y$

The notation we were in the set of the set o \cdot \cdot

Proposition Let S beaposet and X a subset- Then X can have at most one meet and at most one join.

Proof By P meet and join are clearly unique whenever they exist- If a and b are two meets then we have on the one hand $a \preceq b$ and on the other hand $b \leq a$. I his infers $a = b$.

The following property establishes a link between \preceq and the pair (\wedge, \vee) as actual meet and join-

Property 11 (Consistency property) Let 5 be a poset. Then for all $x, y \in S$,

 $x \preceq y \Leftrightarrow x = \bigwedge (\{x, y\})$ $x \prec y \Leftrightarrow y = \bigvee (\{x, y\})$

nition and a poset in the subset is a method of the subset of the subset has a method of the subset of the sub

Corollary 13 A poset S is a lattice iff every two elements have a meet and join.

Example 14 The powerset $\mathcal{P}(X)$, is a lattice where the meet operator is the intersection \Box and the join operator is the union \cup . Every two elements x,y of $\mathcal{P}(X)$ have a meet $x \cap y$ and a join $x \cup y$.

The partial order as set inclusion \subseteq satisfies the consistency property:

 $x \cup y = y \Leftrightarrow x \subseteq y \Leftrightarrow x \cap y = x$

This equivalence defines the correspondence between the relational definition of the structure in terms of properties of the partial order (existence of a glb and a lub) with the algebraic one (properties of the operations).

Definition 15 A lattice L is distributive iff for every x, y and $z \in L$ we have:

$$
x \wedge (y \vee z) = (x \wedge y) \vee (x \wedge z)
$$

Example The powerset lattice is a distributive lattice-

4.1.2 Intervals as lattice subsets

Reasoning with and about intervals within a powerset lattice constitutes the core of our language- the following denimies and properties give the basic properties and properties and of intervals intervals in the species-by two delimited by is species that we have a possible two elements are \sim \sim \sim \sim \sim \sim \sim

— secure is a lattice interval of two arbitrary elements x-p in a lattice is the set $|x \wedge y, x \vee y|$.

Definition 18 A subset 5 of a lattice L is convex if $x, y \in S$ imply

 $|x \wedge y, x \vee y| \subseteq S$

Corollary 19 A convex subset of a lattice is itself a lattice.

Corollary 20 A closed interval $|x \wedge y, x \vee y|$ is convex.

Example 21 Let 5 be a subset of the powerset $P(X)$. For every two elements $x, y \in S$ we have $|x + y, x \cup y| \subseteq S$. I his interval is convex. Furthermore it is unique since the meet and join of x and y are unique.

Property 22 The meet and join operators in a lattice are isotone (preserve the order

 $x \frown y \Rightarrow x \wedge z \frown y \wedge z$ $x \preceq y \Rightarrow x \vee z \preceq y \vee z$

Example 23 This property is extremely useful when reasoning about intervals in a powerset lattice $P(\Lambda)$. Consider the following inclusion relations between elements of $P(X)$:

 $a \subseteq x \subseteq b$ and $c \subseteq y \subseteq d$

 \mathcal{A} and \mathcal{A} belong to the respective intervals \mathcal{A} and \mathcal{A} and \mathcal{A} infer $a \cap c \subseteq x \cap y \subseteq o \cap a$ and dually for the union operation. So if x and y are only defined from the intervals they belong to, their union and intersection can be approximated by the new intervals $[a\cup c, b\cup a]$ and $[a\sqcup c, b\sqcup a]$.

Graduations

A graduation is a specific function which maps elements from a partially ordered set to the set of integers. For example, the powerset $P(X)$ is graduated by the cardinality functional part functions given mechanisms give necessary conditions to consider the conditions of the graduations for a given set-

Definition 24 A set 5 provided with an order relation \preceq is graduated if there exists a function f from S to Z (positive and negative integers) which satisfies:

 $x \prec y \Rightarrow f(x) < f(y)$ \prec is a strict ordering, \prec the arithmetic inequality) x precedes $y \Rightarrow f(x) = f(y) + 1$

An element x_i precedes an element x_{i+1} if in the chain of elements $x = x_0 \prec$ $x_1 \prec \ldots \prec x_n = y$ in S there is no other element between them. f is the graduation of S .

The existence of a graduation of a set which does not correspond to a chain e-set of set of set of set of set \mathcal{L} is a lower set is a lower set is a lower semimodular lattice-

de-lattice L is lower semimodular if \mathcal{A} is lower semimodular if \mathcal{A}

 $x, y, z \in L$ $x \succ z$ and $y \succ z \implies z \sqcup i : i \succ x$ and $i \succ y$

Property The lattice of closed set intervals is a lower semi
modular lattice-

Proof The semi-modularity of a lattice of set intervals derives directly from the existence of a lower and upper bound for any two intervals-strict the strict strict strict orderlings $a_1, b_1 \supset z$ and $a_2, b_2 \supset z$, z exists since the interval $a_1 \cup a_2, b_1 \cup b_2$ is one possible value for z. I neit $t = [a_1 + a_2, b_1 \cup b_2]$ satisfies the condition: $t \supset a_1, b_1$ and $t \supset a_2, b_2$.

Consequently there exists a graduation for the lattice of closed intervals-

Property 27 If there exists one graduation of a set, then there exists an infinite number of graduations of this set.

Set intervals in CLP 4.2

Consider a set as an element of a powerset- Take the convex superset of this collection of sets powerset- This convex part denotes a set interval- This con cept of set interval is the means we will use to reason with and about sets in a Constraint Logic Programming (CLP) language . On the one hand, the user manipulates sets in a logic-based language and on the other hand set interval calculus is performed to search for set values-to section is character in the language is character. terized by a set of predened function and predicate symbols needed to deal with sets-condition describes the abstract syntax of the abstract syntax of the algebraic syntax of the al structure of the system called the constraint domain- This is the structure over which set interval calculus is performed.

Abstract syntax and terminology

The syntax of the language comprises the set of predefined function and predicate symbols relative to sets, the set of constants, the variables, etc.

⁻A CLP language is a logicbased language parameterized by its computation domain and more generally by its constraint domain-

The alphabet The set of predefined function and predicate symbols necessary to reason with a sets is the above sets is the alphabet Sets is the alphab

$$
\Sigma_S = \{\emptyset, \cup, \cap, \setminus, \subseteq, \in_{[a,b]}\}
$$

The predicate symbol $\in_{[a,b]}$ applied to a variable s will be interpreted as the double ordering $a \subseteq s \subseteq b$.

Constants and terms The set of constants defines the domain of discourse of the language- It extends the Herbrand universe to provide the concept of set constant.

de-domain of discourse is the domain of discourse is the powerset of discourse is the powerset of discourse is

 $D_S \equiv \nu(\bar{H}_u)$ where \bar{H}_u refers to the Herbrand universe

A set constant is any element from $\mathcal{P}(H_u)$ represented by the abstract syntax $\{e_1, ..., e_n\}$ where the e_i belong to π_u .

Definition 29 A set variable is any variable taking its value in $P(H_u)$.

nition and the set term is defined by a set term is defined by a set of the set of the set of the set of the s

- (1) any set constant a is a set term
- (2) any set variable s is a set term

Definition 31 A set expression 5 of ν_s where S_1 , S_2 are set expressions is $inductively\ defined\ by:$

 $a | s | S_1 \cup S_2 | S_1 \cap S_2 | S_1 \setminus S_2$

Formulas and programs An atomic formula is a first-order atom (or atom) or a predefined constraint built from set terms, function and predicate symbols \cdot - \cdot \cdot

De-nition An atomic formula is dened as follows

ary predicate and the predicate and the predicate and then predicate than 100 predicate and then predicate

A program built from the logic-based language is based on definite clauses of the form

(1)
$$
A: -B_1, ..., B_n
$$
 and (2) $: -G_1, ..., G_n$

where α is an atom atom at α is an atom or constraint atoms or α , α , α , and α a program clause and a program goal- While atoms are not sub ject to a specific interpretation in the language, the predefined constraints characterize the language.

Notations Set variables will be represented by the letters x- y- z- s- Set con stants with a presented by the letters will be represented by the representation of the representation of the sented by the letters m- n and integer variables by v- w- All these symbols can be subscripted.

Computation domain

The computation domain of the language is the powerset algebra $\mathcal{D}_{\mathcal{S}}$ which interprets (over the domain of discourse D_S) the function symbols \cup, \cup, \setminus belonging to Σ_S in their usual set theoretical sense (*i.e.*, ψ is the empty set, \setminus the set difference, -----

The interpreted set union and intersection symbols have the following alge braic properties

Constraint domain

The constraint domain represents the structure of the system over which set in terval calculus is performed to recompute the computation of the computation domains the computation of the co equipped with the predicate symbols $\subseteq, \infty_{[a,b]}$ belonging to \triangle_S and interpreted as constraint relations. The predicate symbol \subseteq is interpreted as the set inclusion and the predicate $\in_{[a,b]}$ is interpreted as the set domain constraint. This relation constrains a set variable to take its value in a specic domain- Since the main idea of the system is to perform set interval calculus we must guarantee that the domain of any set is an interval-

The structure $|\nu_{\mathcal{S}}, \leq|$ describes a powerset lattice with the partial order \subseteq . Any two of its elements a, b have a unique least upper bound $a \cup b$ and a unique greatest lower bound $a \sqcup b$ (cf. section 5.1.1.). The existence of limit elements for any set $\{a,o\}$ belonging to D_S allows us to define a notion of set domain as a convex subset of D_S , that is a set interval $[a\sqcup b,a\cup b]$.

De-nition A set interval domain or set domain is a convex subset of DS**Definition 33** A set interval domain *or* set dom
specified by [a, b] such that $a \subseteq b$ and $a, b \in \mathcal{P}(H_u)$.

nition and the set variable s is said to range over a set of an a-main $\mathbf{H} = \mathbf{H} + \mathbf{H}$ only if $s \in [a, b]$.

The greatest lower bound a of the set domain contains the *definite* elements of s and the least upper bound b contains *possible* elements of s (comprising the definite ones).

Example 33 The constraint $s \in \{3, 1\}, \{3, 1, 3, 0\}\}\$ means that the elements $\overline{3}, \overline{1}$ belong to s and that 5 and 6 are possible elements of s.

Set intervals have been used so far to specify the domain of a set variable-Regarding set expressions the domain of a union or intersection of sets is not a set interval because it is not a convex subset of D_S (e.g. $I = \{\{1\},\{1,3\}\}\cup \{\{\},\{2,0\}\},\$ interval because it is not a convex subset of D_s (e.g. $I = {\{1\}, {1, 3\}} \cup {\{3\}, {2, 0\}}$,
 ${\{1, 3\}, {\{6\}} \in I$ but ${\{\}, {1, 3, 6\}} \not\subseteq I$. It is possible to maintain such disjunctions of domains during the computation but this leads to a combinatorial explosion-This handling of "holes" can be avoided by considering the convex closure of a set expression domained the constraint domain- α the system is denomined in the system is denomined to a system in as the powerset lattice over the convex parts of $P(D_S)$ (convex subsets of D_S), equipped with a convex closure operation-

Definition 50 The set of all convex parts of $P(D_S)$ is a subset of $P(D_S)$ ordered by set inclusion and designated by \mathcal{L} and designated by \mathcal{L}

Definition 3 C The constraint domain CD is the algebraic structure of the lattice !DS of set intervals ordered by set inclusion such that

$$
\mathcal{CD} = [\Omega D_S, \mathcal{D}_S, \subseteq, \in_{[a,b]}]
$$

The set equality can be derived from the double inclusion $x = y \Leftrightarrow x \subseteq y$ and $y \subseteq$ \mathcal{X} .

Convex closure operation. To ensure that any set domain is a set interval, we denne a convex closure operation which associates to any element of $P(D_S)$ its convex convex

Definition 38 The convex closure operation conv : $P(D_S) \rightarrow \text{MD}_S$ is such that \overrightarrow{cov} : $x \rightarrow \overline{x}$ satisfies:

$$
x = \{a_1, ..., a_n\} \to \overline{x} = \big[\bigcap_{a_i \in x} a_i, \bigcup_{a_i \in x} a_i\big]
$$

Example 39 The convex closure of the set₁₃, $\{3, 2\}$, $\{3, 4, 1\}$, $\{3\}$ belonging to $P(D_S)$ is the set interval $\{\{3\},\{1,2,3,4\}\}\$.

Property 40 An element x of $P(D_S)$ is convex under the above convex closure operation when x is equal to its "closure" \overline{x} .

Corollary 41 All singleton sets are convex.

In the following, the operations $\bigcap_{a_i \in x} a_i$ and $\bigcup_{a_i \in x} a_i$ will be respectively written $glb(x)$ and $lub(x)$ which stand for greatest lower bound and least upper bound of x , respectively.

. The operation convex is a strong of the following \mathbf{r} and \mathbf{r} is a strong interval of the following \mathbf{r} properties

If we consider the \subseteq relation as a logical implication, the extension property C1 can be interpreted by "any element of x belongs to \bar{x} (thus to $qlb(x)$) and any element denimies, met in allows the lubby does not belong to allow the this does not be set calculus to be performed in \mathcal{Q} while ensuring that the computed solutions of \mathcal{Q} are valid in ν_S . Property \cup s guarantees that the partial order \subseteq is preserved in !DS -

 $D = D$ equipped with the operation convex us to denote the constraints us to denote the constraints us to denote the constraints of D domain from the unique function point of view in the union properties of the union and union $\mathcal{L}_{\mathcal{A}}$ intersection operations in 1986 (DS -

Definition 45 The constraint aomain CD is a powerset lattice $\left[D_{\mathcal{S}},\subseteq, \in_{[a,b]} \right]$ with the family is set in the family of set in the set in the set in the set in the set in that satisfaction is set

- P1. Each union of elements of !DS is also an element of !DS
- Each intersection of α is also also and β is also also also also also an D
- $P3.$ $P(D_S)$ and the empty set $\{\}$ are elements of Ω_{S} .

Properties PT and P2 denne the distributivity of \cup and \sqcap in $\mathfrak{u}\nu_S.$ The conditions in P3 denie ΩD_S as a topology on $P(D_S)$. It follows from P2 and the first statement of P_3 ($P(D_S) \in \Omega D_S$) that a convex closure operation satisfying $\cup I$ -C₃ is defined in CD. This operation is conv. Because of PT and P2 this operation satisfies

$$
\overline{x \cup y} = \overline{x} \cup \overline{y}
$$
 and $\overline{x \cap y} = \overline{x} \cap \overline{y}$

Finally P3 implies that $\overline{\emptyset} = \emptyset$.

Set interval calculus

In order to satisfy the properties P P and P we dene a set interval calcu lus with \mathbf{D} -dominations from the following equality relations ordering relations

$$
[a, b] \cup [c, d] \subseteq [a \cup c, b \cup d]
$$
 and $[a, b] \cap [c, d] \subseteq [a \cap c, b \cap d]$

This is achieved by making use of the convex closure operation- The resulting set interval calculus is described as follows

With regard to the set difference operation $[a, o] \setminus [c, a]$, its set theoretical definition is $x \setminus y = x \cap y'$ where y' is the complement of y. The complement of a set interval is characterized only by the fact that it does not contain the elements in the source convex program case-conveys case-convex convex convex convex convex convex convex difference is:

$$
\overline{[a,b]\setminus [c,d]}=[a\setminus c,b\setminus c]
$$

The consistency property $x \subseteq y \Leftrightarrow y = x \cup y$ and $x \subseteq y \Leftrightarrow x = x \cap y$ (cf. 3.1.1) property 11) establishes a link between \subseteq and the set operations of a powerset lattice. This embeds the notions of right inclusion $(y = x \cup y)$, which defines the consistency of y with respect to x, and the left inclusion $(x = x + y)$. Intuitively the right inclusion aims at possibly adding elements to y and the left inclusion at is a set in the consequently if a set interval \mathbb{R}^n and \mathbb{R}^n are set interval \mathbb{R}^n and \mathbb{R}^n the set domain of a set variable x , the right inclusion is applied to a and the left inclusion to b- This is due to the fact that a contains elements which are already in x and b contains possible elements of x.

 \blacksquare assuming that \blacksquare are dominated that \blacksquare and \blacksquare property in CD is defined by:

 $[a, b] \subseteq [c, a]$ \Leftrightarrow $b = b \sqcup a, c = c \cup a$

This definition of consistency is fundamental from an operational point of view- It gives us the necessary conditions to be satised when checking andor inferring consistency of the set inclusion constraint over set domain variables-

$4.2.5$ Graduations

The expressivity of the language can be increased if some "graded" functions are appears to set terms-tre- A graded function mapps a non-top quantizer term to ano integer value denoting a measure of the term- The set cardinality is one example of such a function-deal with optimization-deal with optimization-deal with optimization functions in a set of α α and α in α the constraint domain do presented so far does not contain any such graded functions- In this subsection we extend the alphabet of the language and the constraint domain of the system to deal with such functions- in the function \mathcal{L} is the such the function which maps elements from \mathcal{L} a lattice structure e-quite structure set of integrating is called the set of integers in the set of integers a graduation- Not all lattices can be equipped with graduations- One sucient condition for this is that the lattice is that the lattice is lower semimodular cf-cf-cf-cf-cf-cf-cf-cf-cf-cf-I his is the case for $|\nu_{\mathcal{S}}, \subseteq|$ and for $|\nu_{\mathcal{S}}, \subseteq|$.

In order not to limit the extension of the language to the set cardinality function, the general case of an arbitrary graduation f is studied.

Definition 45 A graduation f is a function from $\vert \nu_{\mathcal{S}}, \leq \vert$ to \mathcal{Z} (set of positive ana negative integers) which maps each element $x \in D_S$ to a unique in such that $f(x) = m.$

The convex closure of a graduation f is required to deal with elements from !DS - The closure function written f maps elements from !DS to a subset of the powerset $P(Z)$ containing intervals of positive and negative integers. This subset is designated by $\Omega \mathcal{Z}$.

example as well as a set when μ a life integrating proposition integer-proposition integerthe constraint $s \in \{ \} , \{ 1, 2 \}$. The cardinality function $\#$ is approximated by $\#$. . In this case of the set of the s

Definition 47 Let $f: D_S \to \mathcal{Z}$. The function $\overline{f}: \Omega D_S \to \Omega \mathcal{Z}$ is derived from f as follows:

^f a- b f a- f b

Property 48 If $x \in [a, b]$ then $f(x) \in f([a, b])$.

Proof. By definition f is a graduation. So if $a \subset x \subset b$ then we have $f(a) \leq$ $f(x) \leq f(\theta)$. Consequently $f(x) \in [f(a), f(\theta)]$ which means $f(x) \in f([a, \theta])$.

This property guarantees that the output of the function \overline{f} applied to a set domain contains the actual graduation value of the concerned set variable-

4.2.6 Extended constraint domain

Graduations add expressive power to the language- They can be embedded as predefined symbols in the language, if the constraint domain is extended to deal with integer integer variables-integer variableswith integer intervals is that of integer interval domains (subset of the standard constraint domain over nite integer domains- It is dened by the structure

$$
\mathcal{FD} = [\Omega \mathcal{Z}, (\mathcal{Z}, +), =, \neq, \geq, \in_{[m,n]}]
$$

where the relation $\in [m,n]$ is interpreted in $\Omega \mathcal{Z}$ as the integer domain constraint such that: $x \in_{[m,n]} [m,n]$ is equivalent to $m \leq x \leq n$. The other symbols are interpreted in their usual arithmetic sense- The extended constraint domain of our system should contain FD .

Definition 49 The extended constraint domain \mathcal{CD}_e with graduations, is the structure $_{b}$] \cup ${\cal FD}$

$$
[\Omega D_S, \mathcal{D}_S, f, \subseteq, \in_{[a,b]}] \cup \mathcal{FI}
$$

 \mathcal{CD}_e interprets graduation symbols as unary set operations with respect to their intended meaning- For example the symbol is interpreted as the set car dinality operation.

Execution model 4.3

The execution model is based on constraint solving in \mathcal{CD}_e . It is a top-down execution model which density the model semantics of the model semantics of the system of the systemdescribes now the constraints are processed over \mathcal{CD}_e and what they lead to. Since $$ the set satisfiability problem is \mathcal{NP} -complete, it is a fortiori \mathcal{NP} -complete in \mathcal{CD}_e . For eciency reasons partial constraint solving is therefore required- The idea consists in transforming a system of constraints in $\mathcal{C}\nu_e$ as follows. Let each set variable range over a set domain- The transformation of a system of constraints in \mathcal{CD}_e aims at removing some values of the set domains that can never be part of any feasible solutions is achieved by making use of constraint satisfaction and constraint satisfactions of techniques.

A transformed system is commonly called a consistent system- One necessary condition for dealing with constraint satisfaction techniques is that each set vari able ranges over a set domain- This section denes the various consistency notions for each predefined constraint in the system, gives the transformation rules used to infer consistency and describes the operational semantics of the system as a transition system on states-

De nition of an admissible system of constraints

The set of predenned constraints in \mathcal{CD}_e can contain any of the following:

- \bullet set domain constraints $s \in [a, b]$ where s is a set variable.
- **•** set constraints $S \subseteq S_1$ where S, S_1 are set expressions (comprising constants, variables and possibly set operation symbols in $\{\cup, \cup, \setminus\}$).
- \bullet graduated constraints $f(S) = |m,n|$ where f is any predentied graduation and any element in the set of \mathbf{A} domain).

Definition 50 An admissible system of constraints in \mathcal{CD}_e is a system of constraints such that every set variable s ranges over a set domain.

From n-ary constraints to primitive ones

The predefined constraints imight denote n-ary constraints like $s_1 \cup s_2 \subseteq s_3 \sqcup s_4$. The partial solving of constraints requires us to express each set variable in terms

of the others. Since there is no inverse operation for \cup, \cup, \setminus there is no way to move all the operation symbols on one side of the constraint predicate- So it is necessary to decompose n-ary constraints into primitive ones.

Consider the following set of basic set expressions $\{s + |s_1, s \cup s_1, s \setminus s_1\}$. The proposed method consists in approximating each basic set expression by a new set variable with its appropriate domain- The resulting constraints are binary or unary ones called primitive constraints-

De-nition A primitive constraint is a predened set constraint contain ing at most two set variables or a graduated constraint containing at most one set variable.

In the former example the n-ary constraint is approximated by the system of constraints

$$
s_1 \cup s_2 = s_{12}, \ s_3 \cap s_4 = s_{34}, \ s_{12} \subseteq s_{34}
$$

This approach is similar to the relational form of arithmetic constraints over real intervals introduced by Cleary Cle -

A relation denoting a basic set expression represent a subset of the Cartesian product of the set domains attached to each set variable- In order to deal with the consistency of these relations, we define projection functions which allow each set domain to be expressed in terms of the others. Consider a relation $r \subseteq$ $|a_1, b_1| \times |a_2, b_2| \times |a_3, b_3|$. The set it denotes must belong to the domain ΩD_S over which the computations are performed-definitions are performed-definitions of D each value of a projection function must be a convex set, that is a set interval. \Box to each problem function function designated by \Box associated by associate its consequent of \Box i- The closure is derived from i by making use of the closure operator dened above which satisfies:

$$
\overline{\rho_i} = \overline{conv}(\rho_i)
$$

 i represents the approximation of this pro jection of the relational form ^r on the s_i -axis.

 \blacksquare the projection function f is a relation f and f pression is the mapping

$$
\overline{\rho_i} = c \vec{on} \, v \, \{s_i \in [a_i, b_i] \mid \exists (s_j, s_k) \in [a_j, b_j] \times [a_k, b_k] \text{ such that } j, k \neq i \, : \, (s_i, s_j, s_k) \in r \}
$$

These relational forms of set expressions are not visible to the user but they are necessary to define the consistency of an n-ary constraint.

Consistency notions

The consistency notions provide necessary conditions to ensure the partial satis faction of primitive constraints- The standard notions of consistency applied to integer domains state conditions that must be satisfied by each element belonging to a variable domain- This approach is not useful to us since set domains specied by set intervals can contain an exponential number of elements (in the size of the powerset described by the domain bounds- Instead we derive conditions that must by satisfaction bounds-by the domain bounds-bounds-bounds-bounds-bounds-bounds-bounds-boundsany relation which does not hold for the bounds of the variable domains will not hold for any element between these bounds- Consider a set variable s- The lower and upper bounds of the domain of s will be respectively defined by the functions glbs and lubs- The upper letters S- S denote set expressions-

Preliminary de-nitions With regard to the consistency properties of the set inclusion constraint, the concepts of lower and upper orderings have been informally introduced-the denitions are given here are since they will be office the office the office the office th much use in the subsequent definitions. Assume the following notations: \subseteq_L for the lower ordering and \subseteq_U for the upper ordering.

— concert ordering is the lower ordering is the relations, and relationship is the relationship of

 $a \subseteq_L b \Leftrightarrow \forall x \in a, x \in b$

— concerned a — message ground sets-matrix which sets are relationships in the sets-

 $a \subseteq_{U} b \Leftrightarrow \forall x \notin b, x \notin a$

These preliminary definitions allow us to define the consistency notions for primitive constraints-

Definition 55 Let $s \subseteq s_1$ be a primitive set constraint. We say that this constraint is consistent if and only if:

 $S\cup I$. $g\iota o(s) \subseteq_L g\iota o(s_1)$ and $SC2.$ $l u o(s) \subseteq U$ $l u o(s_1)$.

The consistency of a primitive set constraint is equivalent to the standard no tion of arcconsistency i-e- interval consistency is equivalent to domain consis tency- Correspondingly if a set constraint is an unary constraint its consistency is equivalent to node consistency-

Property A primitive set constraint is consistent if an only if it is arc consistent.

Proof. This property holds because the operations \cup and \cap are isotone. The constraint $s \in [a, b]$ is equivalent to $\forall e_s \in [a, b]$ we might have $s = a \cup e_s$. The isotony of \cup means that $a \subseteq e_s \subseteq o \Rightarrow a \subseteq e_s \cup a \subseteq o$ (since $a \subseteq o$).

Assume the domain constraints $s \in [a, 0], s_1 \in [c, a]$. The set constraint $s \subseteq s_1$ is consistent i

$$
a \subseteq_L c \text{ and } b \subseteq_U d \iff \forall e_s \in [a, b] \ a \cup e_s \subseteq_L c \cup e_s \text{ and } b \cup e_s \subseteq_U d \cup e_s
$$

$$
\forall e_s \in [a, b], \exists e_{s1} \in [c, d], e_{s1} = c \cup e_s \text{ such that}
$$

$$
e_s \subseteq e_{s1}
$$

$$
s \subseteq s_1 \text{ is arc-consistent.}
$$

 \Box

— nition is a primitive graduated constraint f () — primitive consistent in the $SO(3) = f(s) = f(s) + |m, n|$

The consistency of the relational forms of basic set expressions is defined through the consistency of the pro jection functions- Since the set domain of a basic set expression is approximated it is clear that we can not get the equivalent of arc consistency-consistency-consistency-consistency-consistency-consistency-consistency-consistency-"holes" and are not expected to be part of any feasible solution.

Theorem 58 A relation r denoting the relational form of a basic set expression is consistent if and only if each of the projection functions i describing ^r is $consistent.$

— contracted function function of the relation function function function associated to the relation of the relationship $r \leq \Pi_{j\in\{1,\ldots,3\}}[a_j, o_j]$ is consistent iff.

 $S\cup 4$. $g\{i\}(\rho_i) \subseteq_L a_i$ and $o_i \subseteq_U \{u\}(\rho_i)$

Inference rules

The consistency notions define conditions to be satisfied by set domain bounds so that the domain in the domain are irrelevant-distribution of the inferred by moving \sim such elements "out of the boundaries of the domain" which means pruning the . The essential point is the essential point is the essential point is that is the essential point is that we a allows us to provide a domain-domain-domain-domain-domain-domain-domain-domain-domain-domain-domain-domain-do take can be achieved either by extending the collection of *definitive* elements of a set i-e- satisfying the lower ordering or by reducing the collection of possible elements i-e- satisfying the upper ordering- Both computations are deterministic and are derived from the consistency notions-

4.3.4.1 For set constraints

Consider the constraint $s \subseteq s_1$ such that $s \in [a, b], s_1 \in [c, a]$. Inferring its consistency by means of a domain bound reasoning amounts to satisfying the lower ordering by possibly extending the lower bound of the domain of the set variable $s₁$ and satisfying the upper ordering by possibly reducing the upper bound of the domain of s- This is depicted by the following inference rule

I1.
$$
\frac{b' = b \cap d, \quad c' = c \cup a}{\{s \in [a, b], s_1 \in [c, d], s \subseteq s_1\} \longmapsto \{s \in [a, b'], s_1 \in [c', d], s \subseteq s_1\}}
$$

when set is set the set expressions the relations of the relations are created and the relationship component following additional inference rule is necessary to deal with the projection functions-domain function function function $\mathbf{f}(\mathbf{a})$ and an appearing the domain of an single single $\mathbf{f}(\mathbf{a})$ in a set expression, we have:

I2.
$$
\frac{a'_i = a_i \cup c, \quad b'_i = b_i \cap d}{\{s_i \in [a_i, b_i], \overline{\rho_i} = [c, d] \} \longrightarrow \{s_i \in [a'_i, b'_i] \}}
$$

Two additional inference rules describe the cases where the set domain of a set is reduced to one value or is inconsistent

I3.
$$
\frac{a=b}{\{s_i \in [a,b]\}\longmapsto \{s=a\}} \qquad \text{I3'}.\quad \frac{a \supset b}{\{s_i \in [a,b]\}\longmapsto fail}
$$

4.3.4.2 For primitive graduated constraints.

The constraint $f(s) = |m, n|$ such that $s \in [a, b]$ describes a mapping from an element belonging to a partially ordered set to an element belonging to a totally ordered set-consequently it might of the distinct element is the consequent of \mathbb{P}^1 , \mathbb{P}^1 \mathbf{r} is implied that in \mathbf{r} in \mathbf{r} is inferring the constraint the consistency of this inferring the constraint of this inferring the constraint of this inferring term of the constraint of the constraint of α only if a single element in α single element in α constraint-this element exists it corresponds necessarily to one of the domain element of the domain of the do bounds since they are uniquely defined and are strict subset (or superset), of any element in the domain- Thus the value of the graduation mapped onto them can not be shared-by mechanism is depicted by the following rules rules π

I4.
$$
[m', n'] = [m, n] \cap \overline{f}(s)
$$

$$
\{ s \in [a, b], \overline{f}(s) = [m, n] \} \longmapsto \{ s \in [a, b], \overline{f}(s) = [m', n'] \}
$$

$$
I5. \frac{n = \overline{f}(a)}{\{ s \in [a, b], \overline{f}(s) = [m, n] \} \longmapsto \{ s = a \}}
$$

$$
I6. \frac{m = \overline{f}(b)}{\{ s \in [a, b], \overline{f}(s) = [m, n] \} \longmapsto \{ s = b \}}
$$

Operational semantics

The inference rules described so far can be applied to individual constraints. The operational semantics shows how to check and infer the consistency of a system of constraints- This system should correspond to an admissible system of constraints- the consistency of such a system from the constraints from the constraints from the const each constraint appearing in it-based operations constraints in ite-cap cap constraints in an one one one one deterministic transition rule which takes as input a goal comprising a collection of (1) set domain constraints A, (2) other constraints C, (3) two sets of atoms G and B and (4) one clause among the possible ones in the program whose head out by $\mid G \mid$ and the remainder of G by \downarrow G. This rule returns a new goal to be solved such that the set of the set of constraints is constraint and possible, there possible to an depicted in the following the notation of the sets atoms from the sets of constraints-

 \mathbf{r} and $a \leftarrow c_1 \vee b$ inier $\leftarrow A_1, U_2 \vee \cup U \cup D$ if $\{ A, \{ \uparrow G = a \} \cup C \cup C_1 \} \longmapsto \{ A_1, C_2 \}$

Figure 4.1 Derivation rule of the operational semantics

The crucial point lies in the inference rule dened in the if statement- The inference rules dened so far deal with one constraint- From inferring of the consistency of one constraint, we move to inferring the consistency of a collection of constraints-time time this inference rule possible possible, transformate that set consistency of some constraints might result from the requirements for domain refinements and thus a replacement of the previous set domain constraints (cf. $I1, I2$ and additionally some constraints might be simplified which leads to a transformation of the set of other constraints cf- I I I
- This inference rule corresponds to a set of simple rules which describe the process in more detail-

The process amounts to considering a transition system on states where each state contains the new constraints as yet unconsidered, the (set, integer) domain constraints and the constraints which have already been checked out- One state is specified by a tuple $(U, A_s \cup A_i, S)$ containing the following collections of constraints

- A set of as yet not considered constraints designated by C
- A set of set domain constraints designated by A_s ,
- A set of integer domain constraints A_i ,
- A set of consistent constraints S-

as a constructed to a second the construction of the construction of the construction of the constraint storedo not need to be distinguished their union is denoted A- The initial state of the transition system is $(C, \varnothing, \varnothing)$ where all the constraints need to be checked.

The inference rule in the **if** statement contains different configurations of state transition- For example one transition might be that the consistency of one con straint is inferred without any requirement for domain modification, or that it requires domain refinements which leads to the inconsistency of some already stored constraints- the following set of transition rules to the various to the various to the various possible transformations which are derived when checking or inferring consistency of one constraint in conjunction with the constraint store- the store- the constraint tion rules deal with consistency checking and the last two with the consistency inference.

T1.
$$
\langle C \cup c, A_s, S \rangle \longrightarrow_c \langle C, A_s, S \cup c \rangle
$$

if c is consistent in conjunction with the set As and consequently with the con

T2.
$$
\langle C, A, S \rangle \longrightarrow_c \text{fail}
$$

if at least one set on transition is derived if the inference rule I3' succeeds over at least one set domains constraintent a similar inference rule for the case of integer domains is quite the strain straightforward and corresponds to the case where $x \in [m,n]$ and $n > m$.

T3.
$$
\langle C \cup c, A_s, S \rangle \longrightarrow_i \langle C, A'_s, S \cup c \rangle
$$

if the consistency of c is inferred by requiring a pruning of some set domains thus requiring to modify the set of set derived if any of the inference rules $I1$, $I2$ and $I3$ is successfully applied.

T4. $\langle C \cup c, A_s \cup A_i, S \rangle \longrightarrow_i \langle C, A'_s \cup A'_i, S \cup c \rangle$

if the consistency of c is inferred by requiring a pruning of some integer domain $\begin{array}{ccc} \textcolor{blue}{\mathbf{1}} & \textcolor{blue$ get modified.

state of the transition system is either fail or (\emptyset, A', S') .

Theorem A system of constraints S is consistent if and only if al l the domain constraints that it contains are consistent.

Proof This follows simply from the various inference rules- Inferring the con sistency of a system amounts to considering the consistency of each constraint in conjunction with the already consistent ones- The system is detected inconsistent if and only if the inference rule I is successfully applied-

$4.3.5.1$ Satis-ability issue

Ensuring the satisability of a consistent system requires guaranteeing that a solution exists- This is in not possible when an nary set constraint happens to belong to the system since we work on domain approximations- But whenever dealing with and property and binary set constraints property velocities and because being tween set constraint consistency and the usual consistency notions guarantees a solution- the lower or upper bounds of the set domains will always be possible to possible values for the sets- With respect to graduated constraints consistency does not guarantee satisfiability since a consistent graduated constraint $\overline{f}(s) = m$ does not guarantee that some elements of the domain of s might satisfy the constraint.

Theorem A system of set constraints containing only unary and binary set $constraints$ is satisfiable if and only if it is consistent.

Proof. This follows simply from the property 56 which holds thanks to the $\scriptstyle\rm II11011010110$ of the operations \cup , $\scriptstyle\rm II11$. $\scriptstyle\rm II$

5 Practical Framework

This section describes the Conjunto language a constraint logic programming language designed and implemented to reason with and about sets ranging over a set domain-is des domain-is des set des sets des sets set dened as an individual complete set den element from a subset of a powerset universe- The functionalities of Conjunto (apart from those of a logic-based language) are set operations and relations from set theory together with some graduations which provide set measures like cardinality weight etc- We describe how these graduations can be reconsidered so as to map set domains to subsets of the natural numbers (finite domains).

The implementation of Conjunto is concerned with the way set calculus is achieved in algorithmic terms-complete solution is an interaction is an interaction is an interaction is a achieved in algorithmic terms. Searching for a complete solution is an intractable
problem since set satisfiability is an \mathcal{NP} -complete problem. The basic principle of the Conjunto solver is to check and infer a coherent system of set constraints which guarantees that set values which have been removed from the set domains can never be part of any feasible solution- the many is achieved by adapting local control of the control of th sistency techniques to a domain bound reasoning- Particular attention is given to the description of the local transformation rules which perform domain re nements to infer local consistency of individual constraints- We then describe how the solver which infers/checks the consistency of a system of constraints, handles the calls to these rules by making use of delay mechanisms- Their ade quacy to establish a dynamic cooperation between two solvers Conjunto solver and finite domain solver) is illustrated by the handling of graduated constraints in conjunction with other constraints.

⁻Conjunto means set in Spanish

5.1 Design of Conjunto

This section describes the functionalities of the Conjunto language- We omit a detailed description of the traditional predicates and functions on Prolog terms $[CKC83]$.

Syntax

The Conjunto language is a logic-based programming language with the alphabet of a Prolog language constants predicates functions connectives etc- It is characterized by a signature Σ which contains the following set of predefined function and predicate symbols in their concrete syntax

- \bullet the constant \mathfrak{t} ;
- \bullet the binary set predicate symbols $\{\ \leq, \ \leq\}$, $\ :\ ; \ \#$, weight and arithmetic predicate symbols $\{\equiv, \swarrow, \neq \}$.
- \bullet the binary set function symbols $\{\vee,\vee\}$, $\{\vee\}$ and the arithmetic sum sym $bol +$.

A Conjunto atomic formula is a first-order atom (referred to as atom) or any atomic formula referred to as primitive constraint built from variables function and predicate symbols in Σ .

The language is based on definite clauses of the form:

(1)
$$
a: -b_1, ..., b_n
$$
 and (2) $: -g_1, ..., g_n$

where \mathbf{b} is a is an atom and the bi-following are not constraintssubject to a specific interpretation in the language, the constraints constitute the core functionalities of the language and are characterized by a specific terminology and semantics.

Terminology and semantics

The main objective of Conjunto is to perform set calculus over sets defined as elements from a powerset domain- Some constraints like set cardinality or set weight require us to deal also with finite domains, that is integers and arithmetic constraints.
Definition 62 The computation domain is the set $D = P(H_U) \cup H_U$ where $P(H_U)$ is the powerset of the Herbrand universe.

5.1.2.1 Terminology

The terminology gives names to the predicate and function symbols in Σ and defines the notions of set domains and set terms necessary to reason with and about sets in \mathcal{D} .

The symbols in $\{\times, \times\}$, \colon , $\#$, weight feler respectively to the set inclusion constraint predicate the set disjointness constraint predicate the set domain constraint, the set cardinality constraint predicate and the weight constraint predicate. The symbols in $\{V, V\}$ $\{V, V\}$ represent the concrete syntax of the set operations \cup, \cup, \ldots for other symbols in \vartriangle refer simply to the arithmetic operations they denote-

Definition 63 A ground set is an element of $P(H_U)$ which represents a finite set of Herbrand terms delimited by the characters $\{and\}$.

 \blacksquare

— a set domain is a convex set of ground sets set of ground sets semantically equivalent alent to a set interval-by \mathbf{u} is denoted by \mathbf{u} that $a \subseteq b$.

— concert set domain is a specification is a specific set domain which is a specific set of the set ment of the set domain bounds has the syntax e- m such that e is a Herbrand term and m is an integer.

de-nition and the set variable is a logical variable whose value lies in a set of the set of the set of the set weighted set wontedness in syntaxie to be a changed of

Example of $S = S$ **(Fig. 1), (10, 1), (0, 2), (4, 2)** The a set valiable whose weighted set domain is the set interval $[\{(a,1)\},\{(a,1),(c,2),(d,2)\}]$.

De-nition A set term is a a ground set or a set variable-

nition and nition s is inductively dened by inductively density density density density density denomination of

 $s := t_s + s_1 \wedge s_2 + s_1 \wedge s_2 + s_1 \wedge s_2$

where set is a set that supplementary means a set term

Similarly, variables denoting integers will take their value in a finite set of integers nite domain- In Conjunto these domains are approximated by integer interval domains- An integer interval domain is the convex closure of a nite set of integers and will be simply referred to as an integer interval-

 \mathcal{L} integer interval-

5.1.2.2 Semantics

The interpretation of the elements of Σ in $\mathcal D$ is given by distinguishing set constraints from graduated constraints.

Notation. Conjunto's predicate and function symbols are written in a bold font- Set variables are denoted s- v- w set expressions t integer variables are denoted a-c-denoted a-c-denoted sets a-c-denoted sets a-c-denoted a-c-denoted sets a-c-denoted a-cscripted.

A *primitive set constraint* is one of the following constraints:

- \bullet s \therefore $[a, o]$ is semantically equivalent to $a \subseteq s \subseteq b$
- \bullet s \leq s₁ is equivalent to the set inclusion relation $s \subseteq s_1$.
- \bullet s \leq s₁ is equivalent to the empty intersection of the two sets s, s₁.

Remark The set disjointness constraint \leq which was not included in the formal part has been embedded as a primitive constraint in Conjunto mainly for practical reasons- Since the disjointness of two sets appears in almost all set based problems, it is simpler to use a specific syntax and more efficient to handle it as a primitive constraint.

A *primitive graduated constraints* is one of the following:

- \bullet $\#(s,x)$ is equivalent to the arithmetic equality $\#s \, \equiv \, x$ where $\#s$ is the standard cardinality function of set theory-
- weight(s, x) is semantically equivalent to the arithmetic operation $\sum_i m_i =$ ix such that $(e_i, m_i) \in s$.

 τ cr. the $\in_{[a,b]_a\in b}$ predicate in the formal part.

I he function symbols $\mathcal{V}, \mathcal{V}, \mathcal{V}$ are interpreted as the set operations \cup, \cup, \cup respectively in their usual set theoretical sense- The set dierence is a comple mentary difference (e.g. $s \setminus s_1 = \{x \in s \mid x \notin s_1\}$).

De-nition The constraint system of a Conjunto program is an admissible system- of set constraints and graduated constraints where every set variable is constrained by a set domain constraint-

In this admissible system of constraints the searched ob jects are the sets- The integer variables are not part of the initialization of the search space which is attached to the systems when to the system of the systems to get to the means solution-the following corollary-the following corollary-the following corollary-the following corollary-the following corollary-

Corollary 73 An admissible system of set and graduated constraints is a set domain constraint satisfaction problem i-e-aconstraint satisfaction problem where the initial search space is defined by the set domains attached to the set variables.

Constraint solving

The constraint solving in Conjunto focuses on efficiency rather than on com-The constraint solving in Conjunto focuses on emerging rather than on completeness. Since the set satisfiability problem is \mathcal{NP} -complete, partial constraint solving is required- The Conjunto solver aims at checking and inferring the con sistency of an admissible system of constraints- This is achieved by

- \bullet applying some local transformation rules, which allow the consistency of \bullet one constraint to be checked/inferred, using a top-down search strategy,
- \bullet delaying consistent constraints which are not completely solved.

The Conjunto solver considers one constraint at a time and checks/infers its consistency in conjunction with the set of delayed constraints- This process might require the consistency of some delayed constraints to be reconsidered-These constraints are woken using a data driven mechanism based on suspension handling mechanisms.

The solver acts like a transition system on states- One state is denoted by a tu ple of as yet unconsidered constraints together with a constraint store containing the delayed constraints- Each newly consistent constraint is added to the con straint store- The nal state of the program is achieved when all atoms appearing in a goal clause have been checked and when no further domain refinement is

⁻ci, dennition in the formal part $\mathfrak{d}.\mathfrak{d}.1$

requires state is either denoted by failure is either constraints have been some constraints in a some constra marked inconsistent or it contains a set of delayed constraints together with the set variables and their associated domains.

Example 74 The goal:

 $S : S': [1\{1\}, \{1, 2, 3, 4\}], S1': [3\}, \{1, 2, 3\}], S' < S1.$

produces the refined domains:

S S S S

and the delayed goal: $S \leq S1$

Example 75 The goal:

 \cdot D \cdot \cdot I I I I \cdot I I \cdot \sim \cdot \cdot T I I \cdot T \cdot D \cdot I \cdot I \cdot

produces the instantiation $S = \{1\}$ and no delayed goal since the initial goal is completely solved.

5.1.4 Programming facilities

One of the application domains we have investigated using Conjunto is the mod elling and solving of set based combinatorial problems- To allow the user to state short and concise programs, some programming facilities have been added to the initial set of primitive constraints- They consist of a collection of constraints de fined from the primitive ones, some predicates necessary to access information related to the variable domains and a builtin set labelling procedure- The most important ones are presented below, others are given in the annexe A.

5.1.4.1 Set constraints

 \texttt{max} set equality to the requirement to be equality to be equality control. straint is simply derived from a double set inclusion: $t \leq t_1, t_1 \leq t$ and is handled as such.

The membership and nonmembership e in s , e notin s are handled in a passive way in the sense that they are considered once e is ground- They are respectively defined in terms of set inclusion and set disjointness constraints if e is ground, and delayed otherwise: $\{e\}$ '< s and $\{e\}$ '<> s.

 \mathbf{r} are given allows allows allow \mathbf{r} and \mathbf{r} all the set \mathbf{r} are set \mathbf{r} the state in the set of to set of to set of to set of to set of the variable and its domain is the union of the set domains or set values attached to the set terms-the means of pairwise unions-the means of the means of the set π constraint does not performance of performance that α and since α and dealing the since α with a collection of set equality constraints over a set variable and the union of two set variables that the user Δ the process is not visible to the set Δ , which is the user equality constraints which are not completely solved appear in the set of delayed goals-

Example The goal

 SSS abc all-unionSSS ab

produces the refined domains:

 $S1 = S1[{1}, {a, b}]$, $S2 = S2[{1}, {a, b}]$, $S3 = S3[{1}, {a, b}]$ and the set of delayed goals

SISA IN SOFT FOUND WHO SEEN SAFE SISANTITION SUPPLIES

 \mathbf{r} are given and constraints allows allows all the set terms are set the set terms in the snaps of disjoint-bound-by means of disjoint-bound-by means of disjoint-bound-by means of disjoint-boundstraints over every couple of si- is the minimum of the global union Δ similar to the global union constraint.

Set domains are represented as abstract data types, and the users are not supposed to access them directly-so two predicates are provided to allow operations are provided to α set domains . $\beta = \alpha$ is equal and $\alpha = \alpha$ is equal to denote a set variable, exemption term is respectively assigned the value of the domain's lower and upper bound. Otherwise it fails.

5.1.4.3 Set labelling

Assigning a value to a set variable is a nondeterministic problem which can be tackled by dierent labelling strategies- Since the Conjunto solver uses partial constraint solving, an adequate strategy should aim at making an active use of the constraints in the constraint store- On the one hand a procedure which would consist in instantiating a set by directly selecting an element from the set domain makes a passive use of the constraints whose consistency is only partial- In the

worst case this process might require considering all the elements belonging to a set domain even if some of them are irrelevant-dependent-dependent-dependent-dependent-dependent-dependentset domain by adding one by one elements to the lower bound of the domain is more minimized to minimize the possible choices to be miditate. The first prediction \sim embedded in Conjunto behaves as follows

refines in the set in a set of the set variables in the set of the set instances of state α it is it is it it is it i \mathbf{A} is a ground set nothing happens \mathbf{A} and following happens-following happens-following \mathbf{A} actions are performed recursively until the set gets instantiated: (1) select an element e from the ground set $lub(s) \, \backslash \, glb(s)$, (2) add the membership constraint e in a to the program: Indo waated constructive which who the solver which is dependent checks its constraint the actual constraint with the actual constraint store- actual constraint storefailure the program backtracks and (3) the nonmembership constraint is added (successfully) to the program so as to remove the irrelevant value e from the additional and points (a) when (a) corresponds to the disturbation and constraints of

```
(e in S ; e notin S)
```
Example 77 Consider the goal:

 $S : S : S : [1, 2, 3]$, refine(S).

The search tree generated during the labelling procedure and covered using a depties in a strategy is described in gure - the strategy of the strategy of the strategy of the strategy of the

The strategy which consists in adding membership constraints to the program aims in particular at making an active use of those graduated constraints whose consistency is only partial**Example 78** Consider the goal:

 \mathbf{S} . The state of \mathbf{F} is the state of \mathbf{S} . The state of \mathbf{S}

The irrelevant branches of the search tree are cut in an a priori way i-e- no useless choice point is created-called-called-attention generating the solving of this goal and is depicted in gure - -

5.1.4.4 Optimization predicates

The notion of optimization is common in problem solving- It aims at minimizing or maximizing a cost function which denotes a specic arithmetic expression- The notion of cost denes a kind of measure or quantication applied to some terms- A set can not denote a quantity and is not measurable-control its possible graduations. are- Thus there are no specic optimization predicates for sets- Existing predicates embedded in a branch and bound search and bound sea be directly applied to expressions over integer intervals occurring in graduated constraints- For example minimizing a set cardinality acts over a set through the link existing between a set variable and its cardinality.

5.1.4.5 Relations and constraints

When dealing with sets, it sounds quite natural to deal with relations and functions as well- Functions are more restrictive than relations since they constrain each element from its DS-domain to have exactly one image. Providing relations at the language level extends the expressive power of the language when dealing

 4 DS-domain stands here for departure set

for example with circuit problems and matching problems originating from Op erations research. In relation theory $|\texttt{r}|\text{ra}$ oo $|\texttt{, a}|\text{ real}$ ton $|\mathcal{K}|$ is represented as a set of ordered pairs (x_i, y_i) such that x_i belongs to the DS-domain d of κ and y_i to its AS-range⁻ a. In other words, a relation κ on two ground sets a and a is a subset of the Cartesian product $a \times a$. Reeping this representation to deal with relations as specific set terms containing pairs of elements can be very costly in memory- Indeed the statement of the Cartesian product referring to a relation requires us to consider explicitly a huge set of pairs- This is very inconvenient-Instead, a relation in Conjunto is represented as a specific data structure which is characterized by two ground sets (DS-domain and AS-range) and a list containing the successor sets attached to each element of DS-domain $\lbrack \text{Ger93a} \rbrack$ $\lbrack \text{Ger93b} \rbrack$. Considering one successor set per element splits the domain of a relation into a collection of set domains- the relation is clearly the union of the union is clearly the union of the successor sets-duced introduced in the one introduced introduced in the seminal \mathbb{F}_q which dealt all centres of the state of there is no explicit notion of set domain-

Definition by Let a relation be $r \, \subseteq \, a \times a$. The successor set s of an element $x \in a$ is the set $s = \{y \in a \mid (x, y) \in r\}$.

— nition is a relation variable relation variable which value is a complete pound term birely and a such that birely and the such a functor of arrangements of a there of $\#a$ set variables s_i such that s_i $\; : \; : \; \bot\} \upharpoonright$ and a,a are two ground sets.

This compound term is associated to a free variable by means of the predicate r bin-r d a-

Example 81 The goal:

 \mathcal{L} is the contract of t

creates the term:

 $R = \text{bird}([Set1\{[\{\}, \{a, b, c\}]\}, \, Set2\{[\{\}, \{a, b, c\}]\}], \, \{1, 2\}, \, \{a, b, c\})$

The definition of constraints applied to relation variables abstracts from stating directly constraints over the set DS-domain and AS-range or over the successor sets- The following constraints have been embedded in Conjunto

 $5AS$ -range stands here for arrival set

- \bullet (*i*, *j*) in_r *r*, (*i*, *j*) notin_r *r* which adds or retrieves pairs to the relation
- \bullet funct(r) which constrains a relation to be a function,
- \bullet inj (r) which constrains a relation to be an injective function,
- \bullet surj (r) which constrains a relation to be an surjective function,
- \bullet $\mathsf{p1}$ (r) which constrains a relation to be an bijective function.

The schema of these constraints is directly derived from their usual interpre \mathbf{f} is using the represented below using the represented below using the represented below using the represented below using the representation of \mathbf{f} the mathematical cardinality operation $\#$, the usual set operation symbols (\cup, \cup) and the arithmetic inequality (\geq) .

These constraints do not require any specific solver since the reasoning is based on the successor set variables-

Example 82 The goal:

:- R bin_r
$$
\{1, 2\}
$$
 --> $\{a, b, c\}$, function(R).

creates the term

```
R = \text{bird}([Set1\{[\{\}, \{a, b, c\}]\}, Set2\{[\{\}, \{a, b, c\}]\}], \{1, 2\}, \{a, b, c\})and the list of delayed goals:
```

```

Setabc  
Setabc
```
Since the created compound term is not visible to the user a collection of predicate relations allow him to access to the properties of the relation

- \bullet succs(r, ι) instantiates ι to the list of successor sets of r.
- \bullet dom (r, s) instantiates s to the DS-domain of r.
- \bullet ran (r,s) instantiates s to the AS-range of r.
- \bullet succ (r, e, s) instantiates s to the successor set of the element e belonging to DS-domain, such that $s = \{x \mid (e, x) \in r\}$.

5.2 Implementation of Conjunto

The implementation of Conjunto was done in the ECL'PS° $|$ ECR94) system which extends the plain Prolog language with features dedicated to the implementation of specifies constraints solvers- the mainless provided at the main features provided at the language level of comprise the attributed variable data structure and the suspension handling pred icates-between $\mathbf H$ and $\mathbf H$ and $\mathbf H$ and $\mathbf H$. If a special data type $\mathbf H$ of a variable with a set of attributes attached and whose behaviour on unication can be explicitly defined by the user in a way that differs from Prolog unification. Attributed variables aim at dealing with specific computation domains distinct from the Herbrand universe- The suspension handling predicates provide means to (1) delay a goal or constraint, (2) store it in a specific list with respect to one or several variables, (3) awake a list of delayed goals when some given conditions are satised- The suspension handling predicates allowed us to implement the data driven constraint handling in Conjunto- In addition the Conjunto solver makes use of the finite domain library of $ECL^{i}PS^{e}$ to deal with integer interval terms (as well implemented as attributed variables).

Set data structure

A set variable is not represented as a standard Prolog variable but as an at tributed variable which is substituted unitative which is substituted unitation algorithmternal representation of ground sets is also given since it influences the time complexity of the transformation rules-the data structure and the internal the internal the internal representation of ground sets are not visible to the user and will be ignored in the description of the transformation rules-

5.2.1.1 Set variable representation

A set variable is an attributed variable comprising the following list of attributes-This structure stores for each set variable all the necessary information regard ing its domain, cardinality, and weight (null if undefined) together with three suspension at the attribute arguments have the following meaning meaning.

- \bullet set dom: $|\mathtt{GID}, \mathtt{LUD}|$ represents the set domain. The user can access it using the built-in predicates glb, lub.
- \bullet card: \circ represents the set cardinality. This attribute \circ is initialized as soon as a set domained to attached to a variable-store integrating-species integers in an integer- It can be accessed and modied using specic builtin predicates from a finite domain library.
- \bullet weight: W represents the set weight. W is intialized to zero if the domain is not a weighted set domain otherwise it is computed as soon as a weighted using specific built-in predicates from a finite domain library.
- \bullet del_gib: $\bf D$ gib is a suspension list that should be woken when the lower bound of the set domain is updated.
- \bullet del_lub: Dlub is a suspension list that should be woken when the upper bound of the set domain is updated.
- \bullet del_any: Dany is a suspension list that should be woken when any set \bullet domain refinement is performed.

5.2.1.2 Ground set representation

The choice for the internal representation of sets is independent of the algorithms, and not visible to the user- However it plays a role in the time complexity of the dierent set operations- In contrast to integer intervals the time complexity for operations on ground sets ($+$, $-$ versus \cup , \sqcap , \setminus) can not be considered as constant for it closely depends on the internal representation of a set- In Conjunto each ground set is represented by a sorted list where the time complexity for any set operation (\cup , \sqcup , \sqcup is bounded from above by $O(Za)$ where a is $\#(w(s) + \# q(\iota(s)$ and s the set with the largest domain.

Since we work essentially on set domains another approach has been tried out which consists in representing a set domain as a boolean vector mapped onto a list containing the upper bound value of the elements-bound is specied in a model is specied in by the set of elements whose corresponding $0-1$ variable has the value 1 or $0-1$, where the lower bound is specied by the set of elements whose correspondence of elements whose correspondence sponding variable has the value - This approach reduces the time complexity of the \cup and \cap operations to $\mathcal{O}(\# lub(s))$ where $lub(s)$ is the largest domain upper bound-due to much larger memory usage due to this leads to the size of th domains used in practice and to the handling of two lists (the list of 0-1 variables and the list of actual values).

From now on, the value of d in the complexity results will always stand for $\#lub(s) + \#glb(s).$

$5.2.2$ Set uni cation procedure

 \mathbf{A} and the species attaches a species to see terms-semantics to set terms-semantics to set terms-semantics to see termsrequires to extend the Prolog unication to the one of set terms- The behaviour of the set unification procedure comprises the following tests and inferences:

- \bullet the unincation of a logical variable and a set variable. The logical variable is bound to the set variable.
- \bullet the unification of a ground set and a set variable. The set variable is instantiated to the ground set if it belongs to its domain-
- \bullet the unincation of two set variables. The two variables are bound to a new \bullet variable whose domain is the convex intersection of the two domains (cf. set interval calculus-domain is empty the unitation fails-domain is empty the unitation fails-domain is empty the unitation fails-
- \bullet the unification of a set variable with any other term fails.

The unification procedure is used in the generic algorithm for a system of Conjunto constraints. It will be implicitly referred to by the connective \leftarrow .

5.2.3 Local transformation rules

Consistency notions for primitive set constraints and graduated constraints have been dened in the formal part cf- --- By making use of these denitions the following transformation rules check and infer the consistency of primitive Conjunto constraints- They are based on interval reasoning techniques which are approximations of the constraint satisfaction techniques- The basic idea consists in pruning the set domains attached to the set variables by removing set values which can never be part of any feasible solution-by adding solution-by adding the removed by adding the removed elements to the lower bound of the domain and/or by removing elements from the upper bound.

$5.2.3.1$ Transformation rules for primitive set constraints

Primitive set constraints are s '< s_1 and s '<> s_1 where s and s_1 denote set variables ranging over a set domain- The transformation rules are depicted in gure --

Consider the set inclusion constraint $s_1 \to s_2$ such that $s_1 \in a_1, s_2 \in a_2$. The transformation rule makes use of the lower and upper ordering of the set inclusion-Making this constraint consistent might require adding elements to the lower bound of the domain d and removing elements from the upper bound of d- The refinements lead to the new domain bounds:

T1. $\mathsf{glb}(d'_1) \leftarrow \mathsf{glb}(d_1)$ lub $(d'_1) \leftarrow \mathsf{lub}(d_1) \cap \mathsf{lub}(d_2)$ $T2.$ glb (d'_2) \leftarrow glb (d_2) \cup glb (d_1) \qquad lub (d'_2) \leftarrow lub (d_2)

Consider the disjointness constraint s_1 s s_2 such that $s_1 \in a_1, s_2 \in a_2$. The only possible refinement aims at removing elements from each upper bound of a set domain which are denited that belong that are dening to the set-office set-officers that the other setis consistent if the refined domains for the variables are:

T3. $\mathsf{glb}(d'_1) \leftarrow \mathsf{glb}(d_1)$ lub $(d'_1) \leftarrow \mathsf{lub}(d_1) \setminus \mathsf{glb}(d_2)$ T4. glb (d'_2) \leftarrow glb (d_2) lub (d'_2) \leftarrow lub $(d_2) \setminus$ glb (d_1)

Figure 5.3 Interval refinement for primitive set constraints

 \pm nanks to the monotony of the set operations \cup , \cup , \cup , the interval reasoning eppers is equivalent to domining reasons that equivalent include the contract of $\mathcal{L}_\mathbf{z}$ the domains is a possible value for the set-

Complexity issues. The time complexity for each transformation is bounded by $\mathcal{O}(d)$ since only one set operation is applied each time.

5.2.3.2 Projection functions for n-ary constraints

Constraints over set expressions have not been dealt with so far- These nary constraints require a special handling mechanism due to the properties of the set operations- If there is more than one set operation in the constraint it is practically impossible to express each set variable in terms of the others, since set operations have no direct inverse- the set of the set of the context of the point $\mathcal{L}_\mathcal{A}$ straints as miniprograms- The approach implemented in Conjunto consists in approximating an n-ary constraint by (1) associating each basic set expression $(s_1 \vee s_2, s_1 \wedge s_2, s_1 \vee s_2)$ with its relational form, (2) applying inductively this process until the nary constraint can be expressed as a binary one- The rela tional forms of set expressions are derived by creating a new set variable whose

domain is approximated by using the set interval calculus- The relational forms correspond to the following constraints

union $(s_1, s_2, s) \leftrightarrow s_1 \vee s_2 = s$ inter $(s_1, s_2, s) \leftrightarrow s_1 \wedge s_2 = s$ diff s- s- \leftrightarrow $s_1 \setminus s_2$ '= s

The local consistency of these 3-ary constraints ensures that no triples satisfying the constraint are excluded-inference is performed using transformation \mathcal{U} rules that make use of the projection functions each of whose describing each set domain in terms of the others cf- formal part --- Each such pro jection uniquely defines a smallest set domain which contains the possible solution valuse- provision productions are relationships are productions are relationships are relationships and are relati depicted in gures - - --

Projection functions associated to the constraint $\texttt{union}(s_1,s_2,s)$ such that $s_1 \in$ $a_1, s_2 \in a_2, s \in a$. To notas also for s_2 .

 $T5.$ $\texttt{glb}(d'_1) \leftarrow \texttt{glb}(d_1) \cup \texttt{glb}(d) \setminus \texttt{lub}(d_2)$ $l_{\text{ub}}(d'_1) \leftarrow \text{lub}(d_1) \cap \text{lub}(d)$ $T6.$ $g1b(d') \leftarrow g1b(d) \cup g1b(d_1) \cup g1b(d_2)$ $l_{\text{ub}}(d') \leftarrow \text{lub}(d) \cap \text{lub}(d_1) \cup \text{lub}(d_2)$

Figure 5.4 Projection functions associated to the set union relation

The union of two sets represents a logical disjunction- So it is very unlikely that the addition of new elements to $\text{glb}(d)$ requires modifying the lower bound of the domains of s-case which requires such a renew \mathbf{I} if some elements belong to the lower bound of d and can never belong to one of the two sets consequently the showledge to the other one-should be added to the other one-should be added to the other one-

Projection functions associated to the constraint $\mathtt{inter}_{\{s_1, s_2, s\}}$ such that $s_1 \in$ $a_1, s_2 \in a_2, s \in a$. It. notas also for s_2 .

 $\text{glb}(d'_1) \leftarrow \text{glb}(d_1) \cup \text{glb}(d)$ $l_{\text{ub}}(d'_1) \leftarrow \text{lub}(d_1) \setminus ((\text{lub}(d_1) \cap \text{glb}(d_2)) \setminus \text{lub}(d))$ $T8.$ $glb(d') \leftarrow glb(d) \cup glb(d_1) \cap glb(d_2)$ $l_{\text{ub}}(d') \leftarrow \text{lub}(d) \cap \text{lub}(d_1) \cap \text{lub}(d_2)$

Figure 5.5 Projection functions associated to the set intersection relation

The intersection of two sets represents a logical conjunction- So any addition

of elements to one of the three domains requires modifying at least one of the lower bounds of the domains- A pruning of the upper bound of these domains is rarer-t-might occur in the case depicted in the case of \mathbf{H} which corresponds in Table corresponds in Table to the following configuration: some elements are definite ones of s_2 (or s_1) and possible ones of straighter ones, comment to seems to show they should be removed to show the showledge from the upper bound of the domain of s_1 (respectively s_2).

Projection functions associated to the constraint $\texttt{diff}(s_1, s_2, s)$ such that $s_1 \in$ $a_1, s_2 \in a_2, s \in a$:

Figure Pro jection functions associated to the set dierence relation

The second part of the rule T9 considers a particular case where the upper bound of all should be pruned, if $\pm\pi\pi/\pi$ () contains stemmes which do not belong both to the upper bound of d and to the upper bound of d_2 , then these elements cannot belong to s-1. Both contains made to catholical to prame $\pm \pm \sqrt{m}$

Complexity issues. Time complexity for each transformation rule is bounded by $\mathcal{O}(d)$ times the number of basic set operations, which is bounded by 4 for the

Remark. The relational constraints are transparent to the user at the programming level- However any temporary state of a program is given in terms of these newly created constraints.

Example 83 A partially solved constraint of the form: $S1 \setminus S2$ '< $S2 \setminus S3$

is stored using the set of delayed goals

 $union(S1, S2, S12)$, $inter(S2, S3, S23)$, $S12$ $'$ < $S23$.

5.2.3.3 Graduated constraints: cardinality and weight constraints

Graduated constraints deal with set variables and integer variables- Inferring the partial consistency of these constraints might require refining the integer domains or assignment, a value to a set-construction are not billions are not believe the set-constructions of modification of the integer domains is not a sufficient condition to require a set domain renement- The pruning achieved by the following transformation rules guarantees that (1) the values removed from the domains cannot be part of any feasible solution, (2) if a solution exists, its value lies in the remaining set and integer domains.

Consider the set cardinality constraint $\#(s,x)$ where $s \in a$ and $x \in [m,n]$. x is an integer variable- war integer variable- war integer variable- war integer variable- war integer variable- w

T₁₂. $[m', n'] \leftarrow [m, n] \cap [\# \texttt{glb}(d), \# \texttt{lub}(d)]$ T₁₃. $d' \leftarrow \text{glb}(d)$ if $\# \text{glb}(d) = n$ $T14.$ $d' \leftarrow \text{lub}(d)$ if $\#\text{lub}(d) = m$

Figure 5.7 Transformation rules for the set cardinality constraint

The transformation rules for the weight constraint are similar-dependent are similar-dependent are similar-dependent are similar \mathcal{L} ference lies in the initial computation of the integer intervals-

Consider the weight constraint weight (s, y) where $s \in a, y \in [m, n]$ and <u>Provide a provide a p</u> $e_{(e_k,m_k)\in qlb(d)}$ $m_k = w_{glb}$ and $\sum_{(e_k,m_k)\in lub(d)}$ $m_k = w_{lub}$. We have:

 $T12$. $[m', n'] \leftarrow [m, n] \cap [w_{alb}, w_{lub}]$ $d' \leftarrow \text{glb}(d) \text{ if } m = w_{lub}$ $T13'$. $T14'$. d' \leftarrow 1ub $\left(a\right)$ if $n = w_{ab}$

Figure 5.8 Transformation rules for the weight constraint

5.2.4 Constraint solver

constraint solver applies these rules to check/infer the consistency of an admissible system of constraints in an incremental way- Incrementality refers to the nature of the Conjunto solver which stores each newly consistent constraint and handles the consistency of each constraint in conjunction with the constraint store-

The algorithm Let a tuple collection constraint constraint constraint constraint constraint constraint constraints designated by s- The initial set of constraints to be considered is designated by G-A list C which represents the constraint store contains all the constraints whose consistency and solver selects one constraint constraint constraint c at a time in Grand Co and applies to it the adequate local transformation rule using a depth first search strategy-determined to be constraint c is determined to be constraint if the transformation \mathbf{r} rule infers consistent and might require some domains- and some domains- and consistent and consistent and con consequently a need to reconsider some constraints in C whose variables intersect with those in c-s with the movement with this process \cup to G-1 to G-1 to C-1 to G-1 to G-1 to G-1 to G-1 to resolution is reached once no goal remains in G , or when a failure is encountered $(i.\ell.,$ at least one set domain $[a, o]$ or integer interval $[m, n]$ is such that $a \varphi$ or $m \nsim n$. The program returns the set of constraints \cup which are locally consistent. The general schema of the algorithm is depicted in gure $\mathcal{L}(\mathbf{A})$

begin

```
Initialize G to the list of all the constraints in the admissible system
    Initialize C to the empty list
    while G is not empty do
        begin
             s from and remove the remove the removement (fight process \cupapply the adequate transformation rule on (c, \vec{s}) which returns (c, s')if \vec{s'} is inconsistent then
               exit with failure
                else if \bar{s}\neq s' then
                  begin
                      \vec{s} \leftarrow s'... .... ... . ... . ...
                           if s' \cap \vec{v} \neq \emptyset then
                             remove p-1 from C and a discussion of the C
                  end
                add c-
 s to the end of C-
        end
end
```
This generic algorithm generalizes the complete algorithm we have described in $\left[\text{Ger} 94 \right]$ by moving from the handling of a system containing only primitive set constraints to a system containing any constraint allowed in the language-This algorithm resembles the relaxation algorithm used by CLP(Intervals) systems is the complete the contract of the complete \mathcal{A} and \mathcal{A} are \mathcal{A} . The contract of the contract of of the seen as an adaptation of the AC algorithm \mathcal{M} and \mathcal{M} are dominated the AC algorithm \mathcal{M} mains are specied by intervals-between the algorithms lies between the algorithms lies. in the transformation rules applied-to-transformation rules applied-to-transformation \mathcal{U} properties of fixed point algorithms.

Theorem 84 The algorithm always terminates.

Proof (termination) This comes from the fact that the domains are finite and only get refined: in the different transformation rules, the new lower bounds are computed by extending the former ones (union operation) and the upper bounds are derived by intersecting or removing elements from the form the form ones α inconsistency is detected the algorithm terminates with failure-

Theorem 85 If a solution exists, it can be derived from the simplified system of

Proof This follows directly from the monotony of the convex closure operators⁶ and the inferences performed in the transformation rules-the transformation α that the actual value of a set or integer lies in the approximated domains- The transformation rules aim at removing values which can never be part of any feasible solution- So all possible solution values are kept-

Complexity issues Let l be the size of G and e the size of C- The cost of one transformation rule is bounded by $\mathcal{O}(6d)$ (d being the largest $\#lub(s)$) + $\#glb(s)$). For one constraint the algorithm can be iterated at worst d' times if $d' = \text{\#}lub(s) - \text{\#}glb(s)$. If these iterations are necessary for all the constraints the worst time complexity is then $\mathcal{O}(1dd')$.

This time complexity does not occur in practice- On the one hand if it occurs this means the algorithm leads to a complete solution which is quite rare- On the other hand, the constraints are not systematically reconsidered if some of their variable domains get modied- Indeed the constraints are stored in various suspension lists so as to avoid reconsidering them when there is no need to do so-These lists are described below.

 \lceil Iney have been described in the formal part δ 2.3

5.2.4.1 Suspension lists

Three dierent lists are attached to each set variable- They are meant to improve the time complexity and thus the efficiency of the solver by splitting the list C so that only those constraints concerned with the specific domain refinement are where Γ corresponding to each set variable since μ with domain differentiation of the three thr lists could contain the following goals

- \bullet \mathcal{Q}_{ab} contains the primitive constraints for which a modification of the lower α and α or α and α it contains a constraint requirement on α and α and α constraints of the form σ_l - σ_l .
- \bullet $~Q_{lub}$ contains the primitive constraints for which a modification of the upper \mathbf{I} it contains the constraints-definition the constraints-definition of \mathbf{I} constraints of the form s_j, σ_i sig- σ_j , σ_i and its symmetrical s_j s_i).
- \bullet Q_{any} contains the remaining constraints for which any set domain modication might require reconsidering them- In other words it contains the relational constraints (relational forms of the set union, intersection and difference operations) and the graduated constraints in which the variable si appears-

In addition, the graduated constraints are also stored in the list of delayed \mathcal{W} straints are delayed only once they are attached to two lists and thus might be reactivated with respect to two dierent conditions- This process establishes the dynamic cooperation between the Conjunto solver and the finite domain solver. It guarantees that the partial consistency of a graduated constraint is always maintained within a constraint system-

Execution of a Conjunto program architecture

The Conjunto solver can be embedded in any logic-based language provided a set of constraints solving facilities is given or can be dened-in a medical facilities comprises comprises to (1) attributed variables or a similar structure which links a set variable to its domain and the required lists of delayed goals, (2) suspension handling mechanisms to deal with delayed goals, (3) possibly a finite domain library to tackle set based optimization problems- Figure - presents the execution of a Conjunto program together with the different modules and functionalities required.

Figure 5.10 Execution of a Conjunto program

Tout ce que vous faites maintenant est acte de rêve, pensée de rêve. Que vos rêves soient toujours de plus en plus beaux! Car tout deviendra réalité.

This chapter shows the applicability of the Conjunto language to the modelling and solving of set based search problems- We describe how combinatorial search problems can be modelled as set domain constraint satisfaction problems using the Conjunto language- The focus is on the expressiveness and the eciency of the language when dealing with search problems and optimization problems arising from operations research and combinatorial mathematics-

6.1 Set domain CSPs

The modelling and solving of a set domain CSP follows the usual procedure for CSPs which consists of the problem statement, the labelling procedure and possibly the search for an optimal solution-

$6.1.1$ **Problem statement**

The statement of a set domain CSP amounts to

- \bullet -mitrializing the set variables by assigning a set domain to them.
- \bullet -stating the constraints. The constraints can be set constraints or graduated \bullet graduated constraints restrict the possible set of values a set could take by applying a kind of measure to the set- The set cardinality constraint is used to bound the cardinality of a set to a specific integer domain (or

possibly to an integer-production restricts the sum of the sum of the sum of the integer values appearing in a set domain- These constraints might generate integer variables which are not relevant for the final solution, but which take part in the problem definition and particularly in optimization functions.

Labelling

The labelling phase aims at finding values for the distinguished set variables , the can be done that is those who has the national solution-that which is the national can be done that the by using the pre-defined labelling procedure refine described in the practical framework cf- --- or by dening a new labelling procedure based on specic labelling strategies- An ecient set labelling procedure should not try to directly instantiate a set to one of its domain elements-domain elements-doing so that by doing so that by doing so the satisfaction of those constraints for which only a partial consistency is guaranteed is reached in a passive way- The best method in terms of active use of graduated constraints is based on incremental set domain refinements by adding one by one elements to the lower bound of the set domain (or possibly by removing elements from the upper bound

Optimization

The concept of optimality is related to the notion of minimizing or maximizing a cost function- This function necessarily denotes a measure takes as input an arithmetic expression and returns an integer value- Possible cost functions asso ciated with a set domain CSP are the sum of the set cardinality values, the sum of the weights etc. The weights etc. In the sets via sure and consequently no specific optimization predicate is required to deal with sets-back make user cannot make user can make λ predicates developed for integral cannot domain the sets of CSPs with an optimization criterion- One of these predicates used in a subsequent application (set partitioning), performs the branch and bound search.

The predicate min-maxGoal Cost searches for a solution to the goal Goal that minimizes the value of the linear term Cost using the branch and bound m as a partial dependence operation \mathbf{F} and \mathbf{F} as \mathbf{F} as a partial solution to \mathbf{F} found whose cost is worse than the previous solution the search is not explored any further and a new solution is searched for-

Another predicate is often used to minimize the cost of a solution within a nAcu range, min-max (uval, oost, nin, nax, rereent). This predicate also the assumption that the value Cost to be minimized is less than or equal to

where the solution is solution is to different whose international corresponding the second computer than \sim solution is returned- When one partial solution is found the search for the next better solution starts with a minimized value Percent $\%$ less than the previous one-

The use of these predicates in a set domain CSP requires the definition of Goal as a set labelling procedure call plus a graduated constraint whose integer value is viewed file solving of min-general space and the labelling procedure and incrementally refine the integer domain involved in the graduated constraint. Once all the sets are labelled the integer domain becomes one value (the cost) which can be evaluated by evaluation process will then constraints with the integer \mathcal{M} variable appearing in the graduated constraint to have its value in a new domain whose upper bound is lower than the cost previously computed.

6.2 Modelling facilities

The two problems presented in this section come from the areas of combinatorial mathematics Lue and operations research- The rst one the ternary Steiner problem is to nd a specic hypergraph whose nodes are integer variables- Our approach illustrates how an hypergraph whose nodes are integer variables can be modelled as a simple graph whose nodes are set variables-red problem problem. is a set partitioning problem usually represented by mathematical models and solved integrating integrating programming techniques-britism in the set of the set α domain CSP.

Ternary Steiner problem

The ternary Steiner problem has its origins in combinatorial mathematics- It be longs to the class of block theory problems which deal with the computation of hypergraphs- A hypergraph is a graph with the property that some arcs connect collections of the dest the problem this time add, the collection in computer in computer \sim science- problem for the and the rest time-this problem for the rest time-the rate of problem the rest of the in representing the problem as an integer domain CSP in a constraint logic pro \mathcal{A} is the density of \mathcal{A} is the new concept of \mathcal{A} . The second constraints-ofinteger domain CSP modelling corresponds to the hypergraph representation the integer variables represent the nodes and the global constraints represent the hyperarcs.

Problem statement The statement is taken from [Bel90b]. A ternary Steiner system of order n is a set of $T = n(n-1)/6$ triples of distinct elements in $\{1, ..., n\}$ such that any two triples have at most one element in common The mathematical properties of this propertie prove that it has to the component to be equally a property of \mathcal{L} One solution of Steiner 7 is for example:

 $\{1, 2, 6\}, \{1, 3, 5\}, \{2, 3, 4\}, \{3, 6, 7\}, \{2, 5, 7\}, \{1, 4, 7\}, \{4, 5, 6\}$

The integer domain CSP modelling or hypergraph representation uses three nodes, or variables, ranging over $\{1, ..., n\}$ to represent a triple $\{X, Y, Z\}$. The constraints are μ ordering constraints between the three nodes $\{X \leq Y \leq Z\}$ so as to remove extensive equivalent triples under permutations of the elements $\mathbf{1}$, $\mathbf{1}$, $\mathbf{1}$, $\mathbf{1}$ must have at most one element in common with the other triples of nodes This amounts to constraining each pair of a triple to be pairwise distinct from any other pair appearing in another triple. This requires constraining all the $n(n-1)$ possible pairs $(6$ per triple $[X, Y, Z]$: $[X, Y], [Y, X], [X, Z], [Z, X], [Y, Z], [Z, Y]$ to be pairwise distinct. This approach is sound but far too costly in variables and constraints. A global constraint all-pair-diff has been dened in BelaBelb to free the user from specifying all the pairwise distinct pairs

If each set of three nodes, describing a triple, can be represented as one variable, then the hypergraph corresponds to a graph. This allows the modelling to be simpler and to require less variables Such a modelling corresponds to a set domain CSP approach

Problem modelling Modelling the problem as a set domain CSP involves representing each triple as one set tailward let C_{i+1} . The denote the T set variables which represent the triples Their domains are initialized to the set domain $[{\{\},\{1,\ldots,n\}]}$.

The constraint "any two triples have at most one element in common" is \mathbb{S} . The constraint by \mathbb{S} is summed by \mathbb{S} , \mathbb{S} is summed by \mathbb{S} . Summed by \mathbb{S} up in the short program

```

```
card-constrains the constraints the constraint in the cardinality of the list \sim be equal to
 The predicate intersect-atmost generates the main constraint to be satisfied by each pair of triples.

Problem solving The resolution makes use of the labelling procedure refine(S) for each triple S. If $n = 7$, the first set is instantiated to $\{1,2,3\}$. Then the system tries to instantiate the second set by first adding the element 1 to its lower bound. This domain refinement requires reconsidering the constraint S , S and S by a renewent of the domain of the domain of S by a real S removal of the values - and
 from the upper bound of its domain At this stage in the resolution, the refined domains are:

 $S1 = \{1,2,3\}, S2$:: $[\{1\}, \{1,4,5,6,7\}],$ $[$ S3, S4, S5, S6, S7] $':$ [{}, {1, . . . , 7}].

Computation results The problem was solved in 0.8 sec on a Sun4/40 for α , we choice points were created during the solution step Beldice α Beldiceanu Beldiceanu Beldiceanu Beldiceanu says that - choice points were generated and sec were sucient to solve the problem. This difference in choice points and time was surprising. Unfortunately the global constraint and the program developed were not available and so, in order to make a sound comparison we developed the same program as described in the paper using the $ECL'PS^*$ -integer domain library. The choice points and the time required were then similar to the Conjunto approach but the program was much less natural

The complexity of this problem grows exponentially with n. In [Bel90b] the problem has not been tackled for larger values than 7. Indeed, it turned out that using the same program to solve the problem when $n = 9$ leads to a combinatorial explosion. We defined a labelling strategy which consists in constraining each element to belong to at most $(n-1)/2$ triples. Indeed, there are at most $n-1$ distinct pairs containing one elements which a triple containing this contains - of these pairs In practice this labelling strategy corresponds to a simple occur check before adding one element to a set domain. This does not help when $n = 7$ but for n a following the manufacture of choice points from the consequent composition of the second consequent of the the computation time from time

Remark- For one value of ⁿ there exists more than one solution The search for all the possible solutions requires us to take into account the symmetries inherent to the problem i-e- those which do not depend on the modelling A permutation of two sets does not change the actual solution but corresponds from a computational point of view, to new instances of the set variables. In fact,

the modelling of a search problem as a set domain CSP removes the symmetries that come from an integer domain CSP approach In the Steiner application the solving of the set domain CSP program led to a pruning of the search space which is equivalent to that achieved by the global constraints, aiming at removing local symmetries. Consequently, set constraints resemble some global constraints in terms of problem solving and pruning ability, but to cope with this actual symmetries of the problem a global reasoning on sets is necessary.

The set partitioning problem

The set partitioning problem [GM84] is an optimization problem that comes from operations research Consider a mapping from a set of elements to a collection of equivalence classes each of which contains a subset of these elements, and has a specific cost. The objective is to find a subset of the classes such that they are all pairwise disjoint, each element is mapped onto exactly one class and the total cost of the selected classes is minimal The set partitioning problem resembles the set covering problem, but it is more complex because the disjointness constraints do not guarantee that a feasible solution exists

This problem is currently tackled as a integer linear programming problem using the following mathematical model

$$
minimize (c * x), (a_{ij}) x = e_m
$$

where c is a cost vector $1 * n$, (a_{ij}) is an $m * n$ known matrix comprising 0 and 1 values, x is an $n \times 1$ vector of 0-1 variables and e_m is a vector of m entries equal

$$
\forall i \in Dom, \forall j \in \{1, ..., n\}, \ a_{ij} = \begin{cases} 1 & \text{if } i \in S_j, \\ 0 & \text{otherwise} \end{cases}
$$

 E and E equivalence class is denoted by a set E $\}$

Example 86 A 0-1 modelling corresponds to the following system of constraints: min cx c-x- cx cx cx cx

$$
x_{1} + x_{2} + x_{3} + x_{5} = 1
$$

\n
$$
x_{1} + x_{2} + x_{3} + x_{4} = 1
$$

\n
$$
x_{2} + x_{3} + x_{5} + x_{6} = 1
$$

\n
$$
x_{3} + x_{6} = 1
$$

\n
$$
x_{4} + x_{5} + x_{6} = 1
$$

 \boldsymbol{j}

Each column represents an equivalence class- Each line refers to one element in $\{1, ..., 5\}$. The equality constraints specify that an element can belong to exactly one equivalence class-

Problem statement The mathematical statement of the problem is depicted here in terms of relations and set constraints. Consider a mapping R from Dom to Ran which is constrained to be an application. Let the DS-domain be $Dom =$ $\{1, 2, ..., m\}$ and the AS-range be a family Ran of n subsets of Dom such that $Ran = \{S_1, ..., S_n\}$ where each S_i is an equivalence class (a ground set) and:

$$
\bigcup_{j \in \{1, 2, \dots, n\}} S_j = Dom
$$

A subset P_0 of Ran is a partition of Dom if and only if:

$$
\bigcup_{i \in \{1, 2, \dots, n\}} S_j = Dom \bigwedge \ \ \forall S_j, S_k \in P_0, S_j \cap S_k = \emptyset
$$

 \mathbf{A} cost set \mathcal{L}_{f} is associated to the elements \mathcal{L}_{f} of Randoming a weighted a set composed of elements (S_i, w_i) . The final problem is to determine a partition P^* such that:

$$
\sum_i w_i
$$
 is minimal

This statement corresponds to the approach used with the Conjunto language

Problem modelling Let a relation R on the ground sets Dom and Ran be constrained to be an applicative mapping Each successor set is constrained to be a subset of the proposed sets. These constraints are not sufficient to solve the problem. Two other requirements are necessary:

- the final set P^* of equivalence classes should contain only disjoint sets.
- an instantiated successor set should also represent the successor set of all its predecessors

This corresponds to adding two constraints which will be checked using the for \mathbf{r} is a successor set \mathbf{r} and \mathbf{r} are comes ground inference assuces ground in \mathbf{r} formally, as soon as one successor set $succ(R, i, \{s_k\})$ becomes ground we must have

$$
\forall j \in Dom, \text{succ}(R, j, s_j) \ \left\{ \begin{array}{l} \text{if } j \in s_k, \quad s_j = \{s_k\} \\ \text{if } j \notin s_k, \quad s_j \cap \{s_k\} = \emptyset \end{array} \right. (1)
$$

These constraints correspond to the program

```

disj-or-eq generates the constraints which should be satised by each successor set. It takes as input the application R, its domain Dom and the list of all the successor sets \mathcal{L} and \mathcal{L} is successive distribution of \mathcal{L} is a constraint of \mathcal{L} delayed if the successor set S is not ground, and activated as soon as it becomes ground. The iterate $(S, E, G \circ a)$ predicate is an abbreviation for purposes of clarity only Its role is to apply to each element E in the ground set S the goal Goal At the implementation level it transforms the ground set ^S into a list and iterates over this list

Example 87 The statement of the above example using Conjunto corresponds to the following set of constraints:

```
R bin-
r    
app1(R),
succ(R, 1, S1), S1 \leq {\{1,2,3\}, \{1,4\}},succ(R, 2, S2), S2 \leq {\{1,2,3\},\{2\}},
succ(R, 3, S3), S3 '< \{\{1,2,3\}, \{3,4,5\}\}\,
succ(R, 4, S4), S4 \leq {\{4,5\}, \{3,4,5\}},succ(R, 5, S5), S5 \leq {\{4,5\}, \{3,4,5\}}/* each element i is mapped to a set Si whose domain contains the
   possible equivalence classes (ie. those which contain i) *//* Note that columns 1 and 3 in the ILP modelling correspond here
   to one equivalence class \{1,2,3\}*/
disjon of the state of the state
```
The search space associated to these problems is usually very large and simpli fication rules are applied in order to reduce the initial problem size. An overview

of these rules can be found in HP-removing rows and the found removing rows and the columns in the adjacency matrix formulation. This corresponds to removing, in a deterministic manner, redundant sets from the successor set domains, and to bounding some successor sets to the same variable The main operations amount to checking disjointness and/or inclusion of sets and to computing cliques over the successor set domains

The set of rules corresponds to the following sequences of computations compute the chipac \mathbf{H}_l in the associated intersection graph of R attached to each element ⁱ in Dom This means for each successor set Si attached to i collect all the sets in Ran which have at least one element in common with each set in the domain of S_i ; (2) compute for each $i \in Dom$ the difference set $K_i \setminus \text{lub}(\text{succ}(R, i))$ which contains the irrelevant values and compute the union of all the difference sets; (3) remove from the domain of each successor set S_i such that $j \neq i$, the values which are in the union set

 \blacksquare ing clique is K - The elements removed from the domain of S1 are those in K1 \ lub(S1) that is the set $\{3, 4, 5\}$.

Problem solving One important strength of partial constraint solvers is their dynamic behavior thanks to the delay mechanism For example the re moval of the set $\{3,4,5\}$ from the successor set domains makes it necessary to reconsider the set cardinality constraint over S3 and S5 (cf. appl). The system infers the two instantiations $S5 = \{\{4, 5\}\}\$, $S3 = \{\{1, 2, 3\}\}\$. From these instantiations the system activates the disj-or-eq constraint and infers $S_1 = S_2 = S_3 = \{ \{1, 2, 3\} \}$, and $S_4 = S_5 = \{ \{4, 5\} \}$. In this simple example. the optimal and unique solution is found without any labelling procedure The costs of the various sets does not need to be taken into account

A larger application has been developed, in which it is necessary to look for an optimal solution using the predicate mini-max and to consider a species $\mathcal{U}(\mathcal{N})$ strategy Both require considering an additional set variable which ranges over a weighted set domain. This domain contains all the sets belonging to Ran with their associated cost. Let Sw be this set. The weight constraint weight (Sw, C) forms the basis in the minimization process Additionally the domain of Sw is used in the labelling strategy The strategy aims at selecting a set among the remaining ones whose costs is the lowest

 \mathbf{r} is defining procedure considers each successor set \mathcal{C}_l in order The set \mathbf{r} with the lowest cost which belongs to Sw and to the upper bound of the domain of S_i is selected and added to S_i if we choice point is created and in case of failure

the program backtracks The previous state is restored and the set E is removed from the domain of S_i .

```

To solve the goal labelling (in state) if α the control we recover α the sets instantiate the weight of the set domain of S to its minimal value and then search for a better solution according to the criteria given

 \mathbf{A} set partition results A set partitioning a set partitioning problem describing a set partitioning size x was implemented using the approach presented here The complete program takes 4 pages. The problem was taken from the Hoffman and Padberg library HP- The heuristics led to a simplied problem within seconds and the , the proof of optimal with the proof of optimality required with the proof of optimality required and \sim additional seconds The heuristics removed equivalence classes which enables us to divide the number of choice points by

As far as we know this is the first time a set partitioning problem was modelled concisely, and solved with reasonable efficiency within a logic-based language using constraint satisfaction techniques A modelling using integer domains has be tried, but the programmer gave up due to the difficulties he encountered in representing the heuristics

On the one hand, the flexibility and conciseness of the Conjunto approach is a strength compared with existing mathematical models On the other hand constraint satisfaction techniques are not competitive when compared with global methods like the simplex. For example, the system of Padberg et al. dedicated to set partitioning problem solving solves this problem in less than one second While completing this work, it appeared to us that the set domain CSP approach is promising when investigating feasibility issues that are problematic with the simplex method. The simplex stops when the model is detected to be inconsistent but it cannot detect the reasons for failure The inherent incremental solving of constraint satisfaction techniques can be of a great help In addition the parti tioning problem appears as a sub-problem in numerous real life applications eg timetables, bus line balancing), which are currently solved using integer domain solvers While integer domain CSP are well suited to the scheduling constraints of these problems a set domain CSP can provide an easy way to tackle the partition ing constraints. The cooperation between the solvers is not a problem, provided that the constraints which involve set and integer variables can be attached to both. A real life application is worth considering.

6.3 Efficiency issues: A case study

The previous section illustrated the applicability of the system for dealing with a large class of search problems involving sets, relations, graduations and optimization criteria. The question is: "can a gain in expressiveness be combined with a gain in efficiency \cdot . From a pruning point of view, the one-to-one correspondence between a set variable ranging over a set domain and a vector of variables guarantees that if both sorts of variables are handled using the same labelling procedure $(cf. refine)$, the pruning will be exactly the same. If there is a gain, it might therefore come from the saving in memory utilization and consequently from the garbage collection time This point is illustrated through an integer linear programming optimization problem: the bin packing problem.

Problem description Bin packing problems belong to the class of set par titioning problems [GJ79]. A multiset of n integers $\{w_1, ..., w_n\}$ is given that species the weight elements to partition Another integer Wmax is given that represents the weight capacity. The aim is to find a partition of the n integers into a minimal number of m bins (or sets) $\{s_1, ..., s_k\}$ such that in each bin the sum of all weights does not exceed W_{max} . This problem is usually stated in terms of arithmetic constraints over binary variables and solved using various opera tions research or constraint satisfaction techniques over binary finite domains. It requires one matrix aij to represent the elements of each set one vector xj to represent the selected subsets sk and one vector wi to represent the weights of the elements aij The cost function to be optimized is the total number of bins

in the following figure.

0-1 CSP abstract formulation set domain CSP abstract formulation 0-1 CSP abstract formulation
 $\sum_{i=1}^{m} a_{ij} x_j = 1$ for all $i \in \{1, ..., n\}$ $s_1 \cap s_2 = \{\}, \dots, s_{n-1} \cap s_m = \{\}\$ where:
 $x_i = 0.1 \begin{cases} 1 & \text{if } s_j \in \{s_1, ..., s_k\} \\ 0 & \text{otherwise} \end{cases}$ $s_1 \cup ... \cup s_m = \{(1, w_1), ..., (n, w_n)\}\$ where: s_i :: {}..{ $(1, w_1)$, .., (n, w_n) } otherwise $s_j : \{\}..\{(1)$ $a_{ij} = 0..1 \begin{cases} 1 & \text{if } i \in s_j \\ 0 & \text{if } j \in s_j \end{cases}$ $\sum_{i=1}^n a_{ij} w_i \leq W_{max} \ \forall j \in \{1, ..., m\}$ $\sum_{i=1}^{\# glb(s_j)}$ weight $(i, w_i) \leq W_{max} \ \forall s_j$

Under these assumptions, the program to solve is to minimize the number of bins

$$
\min x_0 = \sum_{j=1}^m x_j \qquad \qquad \min x_0 = \#\{s_j \mid s_j \neq \{\}\}
$$

Problem statement Let $P = \{ (1, w_1), ..., (i, w_i), ..., (n, w_n) \}$ be a non empty set of items i with a weight w_i . The aim is to partition P into a minimal number of ^N bins such that the sum of the wi in a computed subset of ^P does not exceed a limited weight $Wmax$. A bin is represented by a set variable with initial domain $[\{\},P]$. The union of all bins should be equal to P. This is represented using the all-union predicate All the bins should be pairwise disjoint which is represented using the all-disjoint predicate

```
pb-

                                                   restrict_weight(Max, Sets).
```
Problem solving The labelling procedure makes use of the first fit descending heuristic. This heuristic sorts the elements (i, W_i) in decreasing order of their weight. Bins are then filled one after another, which is more efficient than filling all the bins in parallel The optimization predicate is the classical one for packing problems which initially the vite number of bins I, to the value weight of η and increases it at each call of goal predicate in case of failure. The solution is the first successful partition. This program was used to solve a large instance of items partitioned into
 sets The optimal solution was found in about -seconds on a SUN $4/40$.

Experimental results and comparisons A comparative study was made with a integer domain α is a communication implemented using the minister α library of ECLiPSe For the encoding of sets and set constraints we used re spectively lists of binary variables and arithmetic constraints on the variables described previously The arithmetic constraint predicates were handled using the EULiPSe solver of arithmetic constraints over finite domains. The 0-1 $\scriptstyle\rm III$ teger domain program was encoded so as to use the same first fit descending heuristics and the same labelling procedure as the set domain CSP program. The following array gives the results regarding time consumption together with space utilization

The two programs differ in the data structure used, and thus in the constraints applied to these data. The first point to note is that this difference has an impact both on the space usage (stack peaks-) and on the cpu time. The space utilization comprises, among other stacks, the global stack and the trail stack. The data structure is largely responsible for the growth of the global stack peak The difference in space utilization (stack sizes) between the two approaches comes from the set-like representation as a list of zero-one domain variables versus two sorted lists in Conjunto. The lists of zero-one variables are never reduced because

¹ based on consistency techniques which perform a reasoning about variation domain bounds or about variation domains- depending on the constraint predicate

the peak value indicates what the maximum amount allocated was during the session

retrieving an element from a set corresponds to setting a variable domain to zero This is not the case with the set domain representation

The trail stack is used to record information (set domains or lists of zero-one variables) that is needed on backtracking. The number of times the two program execution backtrack is the same, so the difference comes from the amount of information recorded

The garbage collection number is the times garbage collections are performed which is closely linked to the global and trail stack because the garbage collection on both at the same time. Thus, the difference in the garbage collection number comes again from the space utilization

The difference between the cpu times is due first to the time needed for garbage collection which is a direct consequence of the size of the global and trail stack and secondly to the time needed for performing operations on the data.

Profiling the cpu time consumption indicates that half of time spent in the FD program resolution is the time needed for performing arithmetic operations on the zero-one variables. The weight constraint applied to each set is one of the most expensive computations. The weight constraint $a_{i1} \times w_1 + a_{i2} \times w_2 + ... a_{in} \times w_n \leq$ which was wonder that the constant of \mathcal{C} to set to represent the set to denote the constant \mathcal{C} two lists In the Conjunto program it consists in constraining the sum of weights w_i directly available from the elements (v_i, w_i) or a domain upper bound. Another costly computation in the FD formulation is the computation of the largest weight not already considered for one set This requires checking the value of the zero-one variable, and if this value is one, considering the weight associated to this variable A weight is not considered if the corresponding domain variable is not instantiated. In the Conjunto program, this computation corresponds to the difference of the two bounds of a set domain, and the resulting set contains the elements (i, w_i) which have not yet been considered. Computing this difference is in fact the most time consuming step in the Conjunto program resolution because it is also performed when computing disjoint sets but it represents half of the cpu time consumption of arithmetic operations

This application shows that set constraints together with set domains are expressive enough to embed the problem semantics and to avoid encoding the information as lists of binary variables or handling additional data (the list of weights). It also shows that consistency techniques for set constraints are efficient enough to solve combinatorial problems on sets

6.4 Conclusion

In this chapter, we have shown how set based combinatorial search problems coming from combinatorial mathematics and operations research can be modelled and solved using Conjunto. The modelling is based on a set domain CSP approach and the solving on constraint satisfaction and search techniques The solving of set-based optimization problems is possible thanks to the graduated constraints (set cardinality and weight constraints) which map set terms onto quantifiable terms

With regard to an integer domain CSP, a set domain CSP approach contributes transparency with respect to the mathematical denition of set problems and allows the user to go from a hypergraph to a graph representation, thus reducing the number of variables and simplifying the constraint statement phase As far as efficiency is concerned, the first application (ternary Steiner problem) showed that the solving of set constraint achieves a pruning identical to that of global constraints The cpu were also similar This can be generalized to the class of global constraints whose behaviour resembles that of set constraints The second application (bin packing) showed that an efficient set labelling procedure in a set domain CSP, provides a pruning equivalent to the one of the labelling procedure currently used for a social problems even monography and to problems a s variables from a boolean vector the value or in case of failure Consequently any corporation and continuous control continuously using Conjuntor with a possible control of gain in efficiency. The gain comes essentially from the time needed for garbage collection which is more important in the CSP approach which uses a larger amount of variables

The last application (set partitioning) makes us of the one-to-one correspondence between a set variable ranging over a set domain and a vector which allows us to model \mathcal{L} cape in each modelling of the each problems as set domain constraints in a constraint logic programming language shows the programming facilities of logic program ming and enhances the class of CSPs In particular a CSP view of ILPs brings exibility to the modelling and can be useful when $\mathbf{u} \cdot \mathbf{l}$ when \mathbf{l} are to be themself, \equiv , when their feasibility is problematical with ILP tools is \cdots and when small ILP problems are involved in some real CSP applications eg timetables, bus line balancing, etc).

> Du matin au soirne cesse pas d-appeler le Nouveau

In this document, we have described the formal and practical framework of a new constraint logic programming language over sets Its design and implemen tation allowed us to tackle efficiently set-based combinatorial search problems with a natural and concise modelling. The word "natural" is referring to the transparency of the modelling with respect to the mathematical formulation of the problem. The language models set-based problems as set domain Constraint Satisfaction Problems $\left(\text{CSP}\right)$, and solves them using constraint satisfaction techniques. On the one hand, the set domain CSP paradigm extends the standard CSP paradigm to deal with partially ordered domains. On the other hand, we do not lose the pruning power of constraint satisfaction techniques when applying them over set and graduated constraints The applications developed with the Conjunto language showed its practical viability

Today, the Conjunto solver is available as a library in the $ECL^{i}PS^{e}$ platform. developed at ECRC An industrial interest for this solver has appeared while we were implementing the system. Set constraints over set domains are now embedded in the ILOG solver

While our work has essentially aimed at solving applications it has provided us with a matter for a formal definition of the language. The formal framework distinguishes between the computation domain of the constraint logic programming language, and the constraint domain over which the computations are actually performed. These two levels of discourse are linked together by approximations and closure operations. On the one hand, the user reasons on elements from the computation domain. On the other hand, the constraint solver performs computations over elements from the constraint domain. Up to now, $CLP(FD)$ languages are defined as constraint logic programming languages, but their formal definition

is still based on the formal framework defined by Van Hentenryck that is, embedding consistency techniques in logic programming The formal description of the Conjunto language can be used to give a formal definition of CLP(FD) languages in the CLP framework since both systems handle constraints in a similar way

The applications that we have considered are operations research and com binatorial mathematics problems. However, those lasts years the notions of set constraints and set domains have been set for other purposes as well

Related work

A related line of work is program analysis systems HJ AW- BGW [Aik94] among others. They handle a class of sets (possibly infinite sets) larger than that of CLP(Sets) languages or Conjunto, and deal with set constraints of the form $s \subseteq s_1$ where s and s_1 denote specific set expressions (depending on the system at hand). The different resolution algorithms are based on transformation algorithms which preserve the consistency of the system either by computing a least model HJ which does not preserve all solutions or by computing a nite set of systems in solved form AW- In BGW
 the authors demonstrated that the latter algorithm takes non-deterministic exponential time. The difference between these systems and the class of $CLP(Sets)$ languages is that they do not interpret set operations. However, they show the expressiveness of set constraints for the analysis of programs developed in logic programming functional programming, etc.

Another line of research which has some similar points with set domains is the rough set theory Rough sets have been introduced in Paw Paw as a tool for dealing with incomplete knowledge in applications from artificial intelligence (decision systems, pattern recognition, approximate reasoning, etc.). In order to reason on imprecise data in an information system, rough sets approximate the data by a pair of sets similar to the set domain concept. The idea consists in representing an information system as a data table which contains partial information about some objects in terms of attribute values. The row indices of the data table contain the set of objects and the column indices, the list of attributes. The attribute values intersect rows and columns to describe the partial information which characterizes the objects. In general, any pair of objects in an information system may have identical values for some attributes. Such similarities among objects are reflected by a relation called the "indiscernability relation". It is an equivalence class over the sets of objects (called the universe). This relation is used to define approximations of sets of objects from the universe. Two types of approximations are defined, the lower and upper approximations. Each of these

approximations tells us whether a set of object can be characterized by a given set of attributes. The lower approximation contains the set of objects which can be definitely characterized by the attributes and the upper bound contain the set of ob jects which might be characterized by the attributes If some ob jects being in the upper bound do not appear in the lower one this means that they are described by the same attribute values, and consequently can not be characterized by this set of attributes. The concept of rough sets differs from that of set domains essentially in two points. On the one hand, rough sets derive approximations from an external parameter which is the class of attributes considered On the other hand, the approximations are not used to search for variable values, but to answer the following questions If a set of ob jects can not be characterized in an information system can it be approximately characterized ? Is the whole knowledge necessary to describe an information system ? To which extent can we reduce it while keeping the initial information?

Further developments

Some issues are still open with respect to "what we did not do and remains to be done". We believe that some further research on applications and algorithms is needed

Applications The concept of graduated constraints helped us with tackling set based optimization problems and studying the cooperation between two solvers (Conjunto and integer domain solvers), but the search space was defined with set domains essentially The Conjunto language has not been used so far to tackle real life applications defined over a search space containing also integer domains. Applications involving scheduling constraints and set constraints are still to be developed. In particular, they would allow us to figure out whether it is possible or not to work on a mixed-search space. Time tables, bus line balancing, are some of the applications

Another point that has not been considered yet, is the use of the language to deal with other application domains like databases In recent years linear constraints and constraint solving techniques over tuples of relations have been respectively embedded in constraint databases and query languages The main motivations are respectively $\{ \bullet \}$ in the constraints to modelling constraints to model and in relations - to use consistency techniques mainly forward checking for query optimization. The former approach $(see [KKR90])$ considers linear constraints to model some classes of databases $(e.g. in graphics)$. In the latter approach, a

constraint in a database query is a condition that must be satisfied by answers to the query (see [WBP95]). One can think of using set constraints in the former approach to model other sorts of databases In the second approach set constraints could be used to state queries over collections of tuples

Algorithms Regarding the class of consistency methods we have been using we have essentially considered node and arc consistency techniques applied to set and graduated constraints. It sounds interesting to go beyond this, to use path consistency algorithms and to take into account the latest researchs on the topology of constraint graphs. Some issues might be different from those already established with respect to integer domain CSPs. In this respect, the study of the ratio complexity/pruning is very important.

Future work

More work has to be done on extending the class of graduated constraints Currently they map set domains to integer domains that is a partially ordered structure to an ordered one It could be interesting to consider mappings on two partially ordered structures for example from sets to real intervals or vice versa This would extend the expressivity and the application domain of the language This requires studying the formal properties of such mappings and the nature of their closure which deal with elements from a powerset of convex parts It also requires studying their handling when using constraint satisfaction techniques in particular the degree of pruning achieved during the resolution is an important issue with respect to a practical use of these mappings

It would also be interesting to extend the set domain concept to that of lattice domains When solving set partitioning and Steiner problems we realized that if lattice domains and lattice inclusion constraints had been provided, the handling of a set of equivalence classes in the partitioning problem would have been eas ier. For example, considering the lattice domains $\{\{1,3\},\{1,2\}$ $\{\{1,2,3\}\}\,$ we have $\{\{1,3\},\{1,2\}\}\subseteq \{\{1,2,3\}\}\.$ In addition, the global reasoning on the e classes in th
sidering the la
}} \sqsubset {{1.2.3 Steiner problem can be achieved in a straightforward way A solution to the ternary Steiner problem modelled with lattice domains and constraints would have been the value of a single lattice variable, and consequently the symmetries generated by possible permutations of triples disappear A set of constraints applied to variables ranging over lattice domains would ease the modelling and solving of set based problems dealing with the search for equivalence classes. They would model a set domain CSP as a lattice domain CSP and thus add a higher

level of expressiveness with respect to set domains. On the one hand, the formal framework corresponding to embedding lattice intervals in CLP can be derived from the one we have presented. On the other hand, the practical framework requires further works describing the algorithms and studying the trade-off between expressiveness and efficiency.

We present the user manual of the set domain library which is currently available in ECL PS . It does not comprise the mapping terms and constraints.

Conjunto is a system to solve set constraints over finite set domain terms. It has been developed using the kernel of $ECL^{p}S^{\epsilon}$ based on metaterms (attributed variables). It contains the finite domain indiary of EUL'PS'. The indiary con junto-pl implements constraints over set domain terms that contain herbrand terms as well as ground sets Modules that use the library must start with the directive

```
 use-
modulelibraryconjunto or  libconjunto
```
For those who are already familiar with the $ECL^{\dagger}PS^{\dagger}$ extension manual this manual follows the finite domain library structure.

Note: for any question or information request, please send an email to carmen@ecrc.de.

$\mathbf{A.1}$ Syntax

- A ground set is written using the characters $\{$ and $\}$, e.g. $S =$ $\{1, 3, \{a, a\}, f(2)\}\$
- A domain D attached to a set variable is specied by two ground sets variable is specied by two ground sets \mathcal{A} $[Glb_s, Lub_s]$
- Set expressions Unfortunately the characters representing the usual set operators are not available on our monitors so we use a specific syntax making the connection with arithmetic operators
	- \sim U is represented by $\sqrt{\ }$.
	- \cap is represented by \wedge ,
	- \setminus is represented by \setminus

$A.2$ The solver

The **Conjunto** solver acts in a data driven way using a relation between *states*. The transformation performs interval reduction over the set domain bounds. The set expression domains are approximated in terms of the domains of the set variables involved From a constraint propagation viewpoint this means that con straints over set expressions can be approximated in terms of constraints over set variables A failure is detected in the constraint propagation phase as soon as one domain lower bound glbs is not included in its associated upper bound lubs Once a solved form has been reached all the constraints which are not definitely solved are delayed and attached to the concerned set variables

$A.3$ Constraint predicates

svar en kontrolle e

attaches a domain to the set variable or to a list of set variables Svar If $Glb \nsubseteq Lub$ it fails. If $Svar$ is already a domain variable its domain will be updated according to the new domain; if $Svar$ is instantiated it fails. Otherwise if $Svar$ is free it becomes a set variable.

$set(?Term)$

succeeds if *Term* is a ground set.

$?S = ?S1$

The value of the set term S is equal to the value of the set term $S1$.

?E in ?S

The element E is an element of S . If E is ground it is added to the lower bound of the domain of S , otherwise the constraint is delayed. If E is ground and does not belong to the upper bound of S domain, it fails

?E notin ?S

The element E does not belong to S . If E is ground it is removed from the upper bound of S, otherwise the constraint is delayed. If E is ground and belongs to the upper bound of the domain of S , it is removed from the upper bound and the constraint is solved. If E is ground and belongs to the lower bound of S domain, it fails.

$?S$ $'$ $<$ $?S1$

The value of the set term S is a subset of the value of the set term $S1$. If the two terms are ground sets it just checks the inclusion and succeeds or fails. If the lower bound of the domain of S is not included in the upper bound of $S1$ domain, it fails. Otherwise it checks the inclusion over the bounds. The constraint is then delayed.

. The domains of S and S are distoired and S and S

```
all-
union	Lsets 	S
```
Lsets is a list of set variables or ground sets. S is a set term which is the union of all these sets. If S is a free variable, it becomes a set variable and its attached domain is defined from the union of the domains or ground sets in Lsets

all-disjoint and all-

Lsets is a list of set variables of ground sets. All the sets are pairwise disjoint

\sim such that the state of \sim state \sim state \sim state \sim

S is a set term and C its cardinality. C can be a free variable, a finite domain variable or an integer. If C is free, this predicate is a mean to access the set cardinality and attach it to C . If not, the cardinality of

 $weight(?S, ?W)$

S is a set variable whose domain is a *weighted domain*. W is the weight of S . If W is a free variable, this predicate is a mean to access the set weight and attach it to W. If not, the weight of S is constrained to be W . e.g.

 S^{ϵ} :: $[\{(2,3)\},\{(2,3),(1,4)\}],$ weight (S,W)

returns $W:: 3.7$

$refine(?Svar)$

If Svar is a set variable, it labels Svar to its first possible domain value. If there are several instances of $Svar$, it creates choice points. If Svar is a ground set, nothing happens. Otherwise it fails.

$A.4$ Examples

$A.4.1$ Set domains and interval reasoning

First we give a very simple example to demonstrate the expressiveness of set constraints and the propagation mechanism

```
: - lib(conjunto).
```

```
[eclipse 2]: Car ':: [{renault}, {renault,bmw, mercedes, peugeot},
            Type-
french  renaultpeugeot 
            Choice  Car 
 Type-
french
```

```
Choice = Choice{[{renault}, {peugeot, renault}]}
Car = Car[{renault}, {bmw, mercedes, peugeot, renault}]Type-
french  peugeotrenault
```

```
Delayed goals
           inter-speuder aus de la speugeot renaultbanken de speugeot renaultbanken van de de voorbeeld van de verschap v
                       peugeot, renault}]Choice[{frenault}, {fpeugeot, renault} )
```
yes

If now we add one cardinality constraint

```
[eclipse 3]: Car ':: [{renault}, {renault, bmw, mercedes, peugeot}],
            Type-
french  renault peugeot 
            Choice  Car 
 Type-
french

Choice 
Car = Car{[{peugeot, renault}, {bmw, mercedes, peugeot, renault}]}
Type-
french  peugeot renault
Choice = \{peugeot, renault\}
```
yes

The first example gives a set of cars from which we know renault belongs to. The other labels {renault, bmw, mercedes, peugeot} are possible elements for this set \mathcal{F} the set is ground and \mathcal{F} is ground and \mathcal{F} the set term resulting \mathcal{F} from the intersection of the first two sets. The first execution tells us that renault is element of Choice and peugeot might be one The intersection constraint is partially satisfied and might be reconsidered if one of the domain of the set terms involved changes. The cosntraint is delayed.

In the second example an additional constraint restricts the cardinality of this constraint this constraint is constrainted the Choice set to the Choice set to the Choice set to const fpeugeot, renault E. The domain of this set has been modified so is the intersection constraint activated and solved again. The final result adds peugeot to the Car set variable. The intersection constraint is now satisfied and removed

A.4.2 Subset-sum computation with convergent weight

A more elaborate example is a small decision problem. We are given a finite weighted set and a *target* $t \in N$. We ask whether there is a subset s' of S whose weight is t. This also corresponds to having a single weighted set domain and to look for its value such that its weight is t .

This problem is NP-complete. It is approximated in Integer Programming using a procedure which "trims" a list according to a given parameter. For example, the set variable S^{\prime} :: $\{\}, \{(a, 104), (b, 102), (c, 201), (d, 101)\}\$ is approximated by the set variable S' : $[\{\}, \{(c, 201), (d, 101)\}]$ if the parameter delta is 0.04 $(0.04 = 0.2 \div n \text{ where } n = \#S).$

 $: - 1$ ib (conjunto) .

```
%Find the optimal solution to the subset-sum problem
solve(S1, Sum) :-
       getset(S),
       S1 ':: [{}, S],
       trim(S, S1),construction of the second construction of the sum of the second construction of the second construction of the
       weight(S1, W),
       Cost = Sum - W,min-min-maxlabelling (n - ) ; ; ; ; ; ; ; ;
%The set weight has to be less than Sum
constrain-
weightS Sum 
       weight(S1, W),
%Get rid of a set of elements of the set according to a given delta
trim(S, S1) :-
       set2list(S, LS),
       trim1(LS, S1).
trim1([E | LS], S1) :-
       getdelta(D),
       testsubsumed(D, E, LS, S1).
testsubsumed-
 -
 	 -

testsubsumed(D, E, [F | LS], S1):-
        \epsilon - \epsilon and \epsilonel-mathematic weight where the contract of the
       (We = < (1 - D)*Wf)testsubsumed(D, F, LS, S1);F notin S1,
      testsubsumed(D, E, LS, S1).
 Instantiation procedure
labelling(Sub):-
       set(Sub), \ldotslabelling(Sub):-
        weight- weight-
       X in Sub
```

```
\cdot.
      X notin Sub
    labelling(Sub).
%Some sample data
gets(S):-
     S = \{(a, 104), (b, 102), (c, 201), (d, 101), (e, 305), (f, 50),(g, 70), (h, 102).
getdelta(0.05).
```
The approach is the following: first create the set domain variable (s) , here there is only one which is the set we want to find. We state constraints which limit the weight of the set. We apply the "trim" heuristics which removes possible elements of the set domain. And finally we define the cost term as a finite domain used in the min-max predicate The cost term is an integer The conjunto-pl library makes sure that any modification of an fd term involved with a set term is propagated on the set domain. The labelling procedure refines a set domain by selecting the element of the set domain which has the biggest weight using man-cub X and by and by adding it to the set domain of the set domain bound of the set of the set of the set o When running the example, we get the following result:

 $[eclipse 3]: solve(S, 550).$

```
Found a solution with cost 
Found a solution with cost 
10 backtracks
0.116667
S = \{(f, 50), (g, 70), (c, 101), (e, 305)\}\yes
```
An interesting point is that in set based problems the optimization criteria mainly concern the cardinality or the weight of a set term So in practice we just need to label the set term while applying the fd optimization predicates upon the set cardinality or the set weight. There is no need to define additional optimization predicates

$A.5$ When to variables set and use

The *subset-sum* example shows that the general principle of solving problems using set domain constraints works just like finite domains:

- Stating the variables and assigning an initial set domain to them
- Constraining the variables In the above example the constraint is just a built-in constraint but usually one needs to define additional constraints.
- Labelling the variables i-e- assigning values to them In the set case it would not be very efficient to select one value for a set variable for the size of a set domain is exponential in the upper bound cardinality and thus the number of backtracks could be exponential too A second reason is that no specific information can be deduced from a failure (backtrack) whereas if (like in the refine predicate) we add one by one elements to the set till it becomes ground or some failure is detected, we benefit much more from the constraint propagation mechanism. Every domain modification activates some constraints associated to the variable (depending on the modified bound) and modifications are propagated to the other variables involved in the constraints. The search space is then reduced and either the goal succeeds or it fails In case of failure the labelling procedure back tracks and removes the last element added to the set variable and tries to instanciate the variable by adding another element to its lower bound. In the subset-sum example the labelling only concerns a single set. Although the choice for the element to be added can be done without specific criterion like in the steiner example, some user defined heuristics can be embedded in the labelling procedure like in the subset-sum example. Then the user needs to define his own refine procedure.

Set constraints propose a new modelling of already solved problems or allows like for the *subset-sum* example) to solve new problems using CLP . Therefore, one should take into account the problem semantics in order to define the initial search space as small as possible and to make a powerful use of set constraints The objective of this library is to bring CLP to bear on graph-theorical problems, thus leading to a better specification and solving of problems as, packing and partitioning which find their application in many real life problems. A partial list includes: railroad crew scheduling, truck deliveries, airline crew scheduling, tanker-routing, information retrieval, time tabling problems, location problems, assembly line balancing, political districting, etc.

Sets seem adequate for problems where one is not interested in each element as a specific individual but in a collection of elements where no specific distinction is made and thus where symmetries among the element values need to be avoided (eg. steiner problem). They are also useful when heterogeneous constraints are involved in the problem like weight constraints combined with some disjointness constraints.

User-defined constraints $\bf A.6$

To define constraints based on set domains one needs to access the properties of a set term like its domain its cardinality its possible weight As the set variable is a metaterm i.e. an abstract data structure, some built-in predicates allow the user to process the set variables and their domains modify them and write new constraint predicates

$A.6.1$ The abstract set data structure

A set domain variable is a metaterm The conjunto-pl library denes a metaterm

set with provincial productions in the contraction of the contraction of \mathcal{A} del-band de

This attribute stores information regarding the set domain its cardinality and weight (null if undefined) and together with three suspension lists. The attribute arguments have the following meaning

- set dom The representation of the domain its limit itself as set domains are treated as set and as abstract data types, the users should not access them directly, but only using built-in access and modification predicates presented hereafter.
- card The representation of the set cardinality The cardinality is initialized as soon as a set domain is attached to a set variable. It is either a finite domain or an integer. It can be accessed and modified in the same way as set domains (using specific built-in predicates).
- we ight the set \mathcal{L}_{max} and \mathcal{L}_{max} is intialized to zero \mathcal{L}_{max} is interesting to zero \mathcal{L}_{max} if the domain is not a weighted set domain otherwise it is computed as soon as a weighted set domain is attached to a set variable it can be accessed and modified in the same way as set domains (using specific built-in predicates).
- del-glob as suspension and that show may we would be work as well as well as the showled the set domain is updated
- del-lub a suspension list that should be woken when the upper bound of the set domain is updated
- del-any a suspension list that should be woken when any reduction of the domain is inferred

The attributes of a set domain variable can be accessed with the predicate star<u>-</u> attribute or by unitation in a matching can match

```
attribute-attribute-attribute-attribute-attribute-attribute-attribute-attribute-
        -?->nonvar(Attr),
        Attr = A.
```
The attribute arguments can be accessed by macros from the $ECL^{i}PS^{e}$ structures-blue if the attribute of a set of a set of a set of a set domain variable the dellist can be obtained by

argued to set \mathcal{E} at a set \mathcal{E} at a set \mathcal{E} at a set \mathcal{E} or by using a unification: Attr set with del-glb Dglb

$A.6.2$ **Set Domain access**

The domains are represented as abstract data types, and the users are not supposed to access them directly So we provide a number of predicates to allow operations on set domains

```
set-general en de de de la de la setembre de la construction de la construction de la construction de la const
```
If Svar is a set domain variable it returns the lower and upper bounds of its domain Otherwise it fails

glb $(?Svar, ?Glb)$

If Svar is a set domain variable, it returns the lower bound of its domain Otherwise it fails

$\text{lab}(?Svar, ?\text{Lub})$

If Svar is a set domain variable, it returns the upper bound of its domain. Otherwise it fails.

electric contract of the contr

If E is element of a weighted domain, it returns the weight associated to E . Otherwise it fails.

weight and the company of the second contract of the second c

If Svar is a set variable, it returns the element of its domain which belongs to the set resulting from the difference of the upper bound and the lower bound and which has the greatest weight. If Svar is a ground set, it returns the element with the biggest weight. Otherwise it fails.

Two specific predicates make a link between a ground set and a list.

 $set2list(++S, ?L)$

If S is a ground set, it returns the corresponding list. If L is also ground it checks if it is the corresponding list. If not, or if S is not ground, it fails

$list2set(++L, ?S)$

If L is a ground list, it returns the corresponding set. If S is also ground it checks if it is the corresponding set. If not, or if L is not ground, it fails.

$A.6.3$

A specific predicate operate on the set domain *variables*.

When a set domain is reduced, some suspension lists have to be scheduled and woken depending on the bound modified.

NOTE There are
 suspension lists in the conjunto-pl library which are woken precisely when the event associated with each list occurs. For example, if the lower bound of a set variable is modified, two suspension lists will

be woken: the one associated to a glb modification and the one associated to any modification. This allows user-defined constraints to be handled efficiently. modify-contract the contract of the contract of

Ind is a flag which should take the value lub or glb, otherwise it fails If S is a ground set, it succeeds if we have Newbound equal to S. If S is a set variable, its new lower or upper bound will be updated. For monotonicity reasons, domains can only get reduced. So a new upper bound has to be contained in the old one and a new lower bound has to contain the old one Otherwise it fails

$A.7$ Example of defining a new constraint

The following example demonstrates how to create a new set constraint To show that set inclusion is not restricted to ground herbrand terms we can take the following contraint which defines lattice inclusion over lattice domains:

S_1 incl S

Assuming that S and S_1 are specific set variables of the form S^c : $[\{\}, \{\{a, b, c\}, \{d, e, f\}\}], S_1^{\prime} :: [\{\}, \{\{c\}, \{d, f\}, \{g, f\}\}],$ we would like to define such a predicate that will be woken as soon as one or both set variables' domains are updated in such a way that would require updating the other variable's domain by propagating the constraint. This constraint definition also shows that if one wants to iterate over a ground set (set of known elements) the transformation to a list is convenient. In fact iterations do not suit sets and benefit much more from a list structure. We define the predicate $inc($ S, S1) which corresponds to the following program The program is quite long Extending the solver to bear on lattice domains and constraints over lattices would add a lot of expressivity

```
use-elibraryconductoryconjuntoryconjuntoryconjuntoryconjuntoryconjuntoryconjuntoryconjuntoryconjuntoryconjuntor

```
The execution of this constraint is dynamic is defined in \mathbb{R}^n . The predicate inclusion is called inclusion of the predicate inclusion in \mathbb{R}^n and woken following the following steps

- We check if the two set variables are ground set If so we just check deter ministically if the first one is included (lattice inclusion) in the second one include the checks that any element of a ground set α and a ground set α and α is a set itself in this case) is a subset of at least one element of the second set. If not it fails.
- we check if the rate α set is a set is set the second is a set of the second is a set of the set of α If so check-incl is called over the rst ground set and the upper bound of the second set. If it succeeds, then the lower bound of the set variable might not be consistent any more we compute the new lower bound \mathbf{A} elements from the ground set in it (by using the union predicate) and we modify the bound modify-bound This predicate also wakes all concerned suspension lists and instantiates the set variable if its domain is reduced to a single set (upper bound $=$ lower bound).
- we check is the second set is ground and the rest set is a set variable incl is controlled over the lower bound of the lower bound of the rst set and the rst set and the rst set and second ground set If it succeeds then the upper bound of the set variable might not be consistent any more The new upper bound is computed by

intersecting the first set with the upper bound of the set variable in the lattice acceptation large-inter and is updated modify-bound

- of the first set should be included in the lattice sense in the upper bound in the second one check- $\frac{1}{2}$ it succeeds the lower bound second set is no more consistent we compute the new one by making the union with first sec lower bound. In the same way, the upper bound of the first set might not be consistent any more. If so, we compute the new one by intersecting (in the lattice acceptation) the both upper bounds to compute the new upper bound of the rst set large-inter The upper bound of the first set variable is updated as well as the lower bound of the second set modify-bound
- After checking all these updates we test if the constraint instance \mathbf{r} if the constraint implies and instance \mathbf{r} ciation of one of the two sets. If this is not the case, we have to suspend the predicate so that it is woken as soon as any bound of either set do main is changed The predicate make- any predicate make- \sim $ECLⁱPS^e$ module based on a meta-term structure. It creates a suspension, and the predicate interest in the suspension into the predicate into the suspension into the suspension into t appropriate lists (woken when any bound is updated) of both set variables.
- the last action was the execution of \mathbf{A} the updates we have made These goals should be woken after inserting the new suspension, otherwise the new updates coming from these woken goals won't be propagated on this constraint !

$A.8$ Set Domain output

The library conjunto-pl contains output macros which print a set variable as well as a ground set respectively as an interval of sets or a set. The **setdom** attribute of a set domain variable (metaterm) is printed in the simplified form of just the [qlb , lub] interval, e.g.

```
eclipse Sanction and the Sanction of the Sanct
                             A = set with setdom : D.S = S[{0}, {a, c, v}]A = [\{\} , \{a, c, v\}]D = [\{\}, \{a, c, v\}]yes
```
A.9 Debugger

The $ECL^{i}PS^{e}$ debugger which supports debugging and tracing of finite domain programs in various ways, can just be used the same way for set domain programs. No specific set domain debugger has been implemented for this release.
